## THE MODERN MATHEMATICAL SERIES

## LUCIEN AUGUSTUS WAIT . . . Gemeral Editor <br> (EENIOE PRONESSOR OF MATBEYATIOS IN CORNKLL UNIVEKAITY)

The Modern Mathematical Series.

LUCIEN AUGUSTUS WAIT, (Semar Poufesor of Matbematics in Corsell University.) GENERAL EDITOR.

This series includes the following works:
ANALytic geometry. By J. H. Tanner and Joseph Allen.
differential calculus. By James McMahon and Viroil Snyder.
integral calculus. By D. A. Murray.
differential and integral calculus. By Virgil Snyder and J. I. Hutcminson.
elementary algebra. By J. H. Tanner.
ELEMENTARY GEOMETRY. By James McMahon.

The Analytic Geometry, Differential Calculus, and Integral Calculus (published in September of 1898) were written primarily to meet the needs of college students pursuing courses in Engineering and Architecture; accordingly, practical problems, in illustration of general principles under discussion, play an important part in each book.

These three books, treating their subjects in a way that is simple and practical, yet thoroughly rigorous, and attractive to both teacher and student, received such general and hearty approval of teachers, and have been so widely adopted in the best colleges and aniversities of the country, that other books, written on the same general plan, are being added to the series.

The Differential and Integral Calculus in one volume was written especially for those institutions where the time given to these subjects is not sufficient to use advantageonsly the two separate books.

The more elementary books of this series are designed to implant the spirit of the other books into the secondary schools. This will make the work, from the schools up through the university, continuous and harmonious, and free from the abrupt transition which the student so often experiences in changing from his preparatory to his college mathematics.

## PREFACE

Armiotan in the writing of this book the needs of the students in the various depariments of Engineering and of Architecture in Cornell Eniversity hare reoclved the first consilleration, care has also been taken to make the work suitable for the general student and at the same time usefnl as an introluction to a more advanced course for those students who may wish to speciatize later in mathematics.

Aurong the features of the hook are:
(1) Ais extented introolnction (Chajas. II, III, IV), in which it is hoped that the fondamental prohlems of the subject are clearly set forth and sufficiently illustrated. The chief difficulty which the leginner in Analytic Geometry usually has to overoome is the relation between an equation and its locus; having really mastered this, he ensily and rapidly acquires a knowledge of the properties to whieh this relation leads, and especial care has therefore been given to this matter. Analytic Geometry is broader than Conic Seotions, and it is the firm conviction of the authors that it is far more important to the student that he should acquire a familiarity with the spirit of the method of the subject than that he should be required to memorize the various properties of any particular curve.
(2) The making use of some intrinsic properties of curves (see Arts. 106, 112, 118), which experience with many classes has shown to give the stodent an unusually strong grisp on the equation of the second degree from which the $x y$-term is absent.
(3) Introduction of the demonstrations of general theorems by numerical examples. This not only makes clear to the student what is to be done, but shows also the method to be employed, - it generalizes after the student is acquainted with the particular.
(4) Easy lut rigorous proofs of all the theorema within the scope of the book. E.g., in Art. 67 it is proved, and
very simply, too, that the vanishing of the diseriminant is not only a necessary. but also the sufficient combition that the quadratic equation represents a pair of straight lines.

It may also be mentioned here that, in the early part of the book, two or more figures are given in connection with, a proof and so lettered that the same demonstration applies to each. It is hoped that this will help to convince the student of the generality of the demonstration. A copious index which enables one almost instantly to turn to anything contained in the book has also been added.

The engineering students at Cornell University study Analytic Ceometry during the first term of their freshman year, and experience has shown that it is best to devote a few lessons at the beginning of the term to a rapid review of those parts of the Algebra and Trigonometry that are essential to the reading of the Analytic (ieometry. The first twenty-three pages are devoted to this matter, and may, of course, be omitted by those classes that take up the subject immediately after reading the Algebra and Trigonometry.

The book contains littlo more than can be mastered by a properly prepared student of average ability in from twelve to fourteen weeks; if less than that time can be devoted to the work, the individual 'eacher will know best what parts may be most wisely omitted by his pupils. A list of lessons for a short course of eleven weeks is, however, suggested on the next two pages.

A few specific acknowledgments of indebtedness are made in foot-notes in the appropriate places in the book. Of the large number of examples which are inserted, many are original, while many others have come to be so common in textbooks that no specific acknowledgment for them can be made. We take great pleasure in expressing here our thanks to the other authors of this series of books for their many helpful snggestions and criticisms; to our colleagues, Dr. J. 1. Hutehinson and Dr. G. A. Miller, who have so greatly assisted us in reading the proof, and the latter of whom also read the manuscript before it went to press; to Mr. Peter Field, Fellow in Mathematics, and Mr. E. A. Miller for solving the entire list of examples; and to Mr. V. T. Wilson, Instructor in Drawing in Sibley College, for the care with which he has made the figures.

## L.IST OF L.ESSONS SUGGESTED FUR A SHORT COURSE

[From the various sects of exerciness the teacherr to experted to make melecfioms for sach leswon. The fifth day of each week showald be desoteof to reviewing the greceding four leswins.]

## CONTENTS

PART 1. - PLANE ANAIYTIC GEOMETRY
CHAPTER I
Introntitros
Algeliraie amad Trigonometric Conceptions
anTict1. Number1
2. Constauts and variablem ..... 2
2. Functions ..... 3
4. Ideatity, equation, and root ..... 4
5. Functions classified ..... 4
f. Notation ..... 5
7. Continuous and discontinuons functions ..... 6
8. The quadratie equation. Its solution ..... 9
10. Zero and infinite roots ..... 11
11. Properties of the qualratie equation ..... 12
12. The q̧ualratie equation involving two unknowns ..... 13
Trigonumetric Conceptions and Formulus
13. Directed lines. Angles ..... 15
14. Trigonometric ratios ..... 17
15. Punctions of related angles ..... 15
16. Other important formulas ..... 19
17. Orthogonal projection ..... 21
CIIAPTER II
Giometicic Concemtions. Tue Point
I. Cobindinate Symems
18. Cooindinates of a point ..... 24
19. Analytic Geometry ..... 25
AETMCER ..... Pagis
20. Positive and negative coordinates ..... 25
21. Cartesian conrilinates of points in a plane ..... 26
22. Rectangular coördinatea ..... 27
23. Polar coordinates ..... 29
24. Notation ..... 30
II. Elementary Applications
25. $\}$ Distance between two points
(1) Polar coördinates ..... 31
(2) Cartesian coordinates; axes not rectangular ..... 32
(3) Rectangular coördiuates ..... 33
27. Slope of a line ..... 38
28. Summary ..... 34
29. The area of a triangle
(1) Rectangular coordinates ..... 34
(2) Polar coördinates ..... 36
30. To find the coordinates of the proint which divides, in a given ratio, the straight line from one given point to another ..... 37
31. Fundamental problems of analytic geometry ..... 40
CHAPTER III
The Locus of an Equation
32. The locus of an equation ..... 43
33. Illustrative examples: Cartesian coördinates ..... 43
31. Loci by polar coördinates ..... 46
35. The locus of an equation ..... 47
36. Classification of loci ..... 48
37. Construction of loci. Discussion of equations ..... 49
38. The locus of an equation remaius unchanged: ( $\alpha$ ) hy any trans- position of the terms of the equatio: ; and $(\beta)$ by multiply- ing both members of the equation by any finite constant ..... 52
30. Points of intersection of two loci ..... 53
40. Product of two or more equations ..... i4
41. Locus represented by the sum of two equations ..... 56
CHAPTER IV
Thr Equation of a Locus
42. The equation of a locus ..... 81
43. Equation of straight line through $t$ wo given points ..... 61
A Facs
41. Equations of straight lime through given proint anod ins given direetion ..... 63
4.i. Equation of a circlen; polar conordinates ..... 64
fts. Figation of locus traced by a mosing poiat ..... 65
8.. Fiquation of a circle : meconl method ..... U5
18. The conic sections ..... 6
40. The une of curves in applied mathomatics ..... 73
CHAPTER V
Tur Strabiut Lise. Fequation of Fibet Dxomeg

$$
A x+B y+C=0
$$

60. Recapitulation ..... 81
61. Equation of straight line through two given points ..... 81
6.2. Equation of straight line in terms of the interceptes which it makes on the coördinate axes ..... 83
62. Equation of straight lise through a given point and in a given direction ..... 84
63. Equation of straight line in terms of the perpendieular from the origin upon it, and the angle which that perpendicular makes with the 2-axis ..... 86
64. Normal form of equation of straight line: second method ..... $8 \%$
65. Summary ..... 88
66. Every equation of the first degree between two variables has for its locus a straight lino ..... 89
67. Reduction of the general equation $A x+B y+C=0$ to the standard forms. Determination of $a, b, m, p$, and $a$ in terms of $A, B$, and $C$. ..... 91
68. To trace the locus of an equation of the first degree . ..... 94
etio. Special cases of the equation of the straight line $A x+B y+C=0$ ..... 95
69. To find the angle made by one straight line with another. ..... 97
70. Condition that two lines are parallel or perpendicular ..... 05
71. Line which makes a given angle with a given line ..... 101
72. The distance of a given puint from a given line ..... 105
73. Bisectors of the angles between two given lines ..... 108
74. The equation of two lines ..... 110
75. Condition that the general quadratic expression may be factored ..... 111
76. Equations of straight lines : oven linate axes oblique . ..... 115
77. Equations of straight lines: polar courdinates ..... 118
CHAPTER VI
Transpohmation of Coördinater
paor antices ..... 123
I. Carterian Coobrdinates Only
78. Change of origin, new axes parallel respectively to the original axes. ..... 124
79. Transformation from one system of rectangular axes to another system, also rectangular, and having the same ori- gin; change of direction of axes ..... 126
80. Transformation from rectangular to oblique axes, origia un- changed ..... 127
81. Transformation from one set of oblique axes to another, origin unchanged ..... 128
82. The degree of an equation in Cartesian coördinates is not changed by transformation to other axes ..... 129
II. Polar Coürvinates
83. Transformatious between polar and rectangular systems. ..... 130
CHAPTER VII
The Circle
Special Equation of the Second Degree

$$
A x^{2}+A y^{2}+2 G x+2 F y+C=0
$$

77. Introductory ..... 185
78. The circle: its definition and equation ..... 135
79. In rectangular coördinates every equation of the form $x^{2}+y^{3}$
$+2 G x+2 F y+C=0$ represents a circle ..... 137
80. Equation of a circle through three given joints ..... 138
Secants, Tangents, and Normals
81. Ilefinitions of sepants, tangents, and normals ..... 140
82. Tangents: Illustrative examples ..... 141
83. Enguation of tangent to the circle $x^{2}+y^{2}=r^{2}$ in terms of its slope ..... 142
84. Equation of tangent to the circle in terms of the coördinates of the point of contact: the secant method ..... 144
annimes peses
8.3. Equation of a normal to a given circle ..... 147
as. lengtis of tangents and normals. Sultangents and nut- normaln. ..... 119
8\%. Tangent anal burmal lengthes, subtangont and sulnormal, for the circle ..... 130
8s. To find the lengti of a tangent from a given external point to a given circle ..... 151
85. From any print outaste of a circle two tangents to the circle can bo drawn ..... $1: 2$
(6). Chord of contact ..... 131
86. Poles and polars ..... $1: 3$
87. Equation of the polar ..... $1: 3$
88. Fundamental theorem ..... $15 \%$
89. Goometrical construction for the polar of a given point, and for the pole of a given line, with regard to a given circle ..... 1.8
90. Circles through the internections of two given circles ..... 100
91. Common chorl of two circles ..... 100
92. Radical axis; radical center ..... 161
93. The equation of a circle : polar coordinates ..... 162
94. Equation of a circle referred to oblique axes ..... 163
95. The angle formed by two intersecting curves ..... 164
CHAPTER VIII
The Consc Sectiona
96. Recapitulation ..... 170
I. The Paratola
Special Equation of Second Degree
$A x^{2}+2 G x+2 F y+C=0$, or $B y^{2}+2 C i x+2 F y+C=0$
97. The parabola defined ..... 170
98. First standard form of the equation of the parabola ..... 171
99. To trace the parabola $y^{2}=4 \mathrm{pr}$ ..... 172
1u. Latus rectum ..... 173
10hi. Geometrie property of the parabola. Second stamlard equas- tion ..... 178
100. Every equation of the form
$A x^{2}+2 G x+2 F y+C=0$ or $B y^{2}+2 G r+2 F y+C=0$. represents a parabola whose axis is parallel to one of the coördinate axes ..... 173
101. Reduction of the eguntion of a prarabiola to a standard form ..... 177

## II. The Ellipse

Special Equation of the Second Degree

$$
A x^{2}+B y^{2}+2 G x+2 F y+C=0
$$

antres ..... page
100. The ellipse defined ..... 179
110. The fint standard equation of the ellipse ..... 180
111. To trace the ellipse $\frac{s^{2}}{a^{2}}+\frac{y^{2}}{b^{2}}=1$ ..... 182
112. Intrinsie property of the ellipse. Second standard equation ..... 183
118. Every equation of the form

$$
A x^{2}+B y^{2}+2 G x+2 F y+C=0
$$

represents an ellipse whose axes are parallel to the coördi-nate axes, if $A$ and $B$ have the same sign186
114. Reduction of the equation of an ellipse to a standard form ..... 188
III. The Hyperbola
Special Equation of the Second Degrea

$$
A x^{2}-B y^{2}+2 G x+2 F y+C=0
$$190

116. The first standard form of the equation of the hyperbola ..... 191
117. To trace the hyperbola $\frac{x^{2}}{a^{2}}-\frac{y^{2}}{b^{2}}=1$. ..... 193
118. Intrinsic property of the hyperbola. Second standard equa- tion ..... 195
119. Every equation of the form

$$
A x^{2}+B y^{2}+2 G x+2 F y+C=0
$$

represents an hyperbola whose axes are parallel to the coör-dinate axes, if $A$ and $B$ have unlike signs197
120. Summary ..... 199
IV. Tangents, Normals, Polars, Diameters, etc.
121. Introductory ..... 200
122. Tangent to the conic $A x^{3}+B y^{2}+2 G x+2 F y+C=0$ in terms of the coördinates of the point of contact : the secant method ..... 200
123. Normal to the conic $A x^{2}+B y^{2}+2 G x+2 F y+C=0$, at a given point ..... 203
124. Equation of a tangent, and of a normal, that pass through a given point which is not on the conic ..... 205
A8PML paces
120. Through a given external print two tangenta to a conic can Le drawn ..... 200
1273. Fiquation of a chord of contact ..... 207
1:7. Poles and polars ..... 208
1:8. Fiundamental theorem ..... 210
1:9. Diameter of a conic mection ..... 211
130. Equation of a conte that passes through the intersections of two given comics ..... 218
V. Podar Equation of the Conic Sections
131. Polar equation of the oonic ..... 214
132. From the polar equation of a conic to trace the curve ..... 215
CHAPTER IX
Tue Parabola $y^{2}=4$ px
133. Review ..... 219
131. Construction of the parabola ..... 220
135. The equation of the tangent to the parabola $y^{3}=4 p r$ in terms of its slope ..... 221
13s. The equation of the normal to the parabula $y^{2}=4 p s$ in terms of its slope ..... 222
13\%. Sultangent and subnormal. Construction of tangent and normal ..... 222
138. Some properties of the parabola which involve tangents and normals ..... 225
139. Diameters ..... 230
140. Some propurties of the parabola involving diameters ..... 232
141. The equation of a parabola referred to any diameter and the tangent at its extremity as axes ..... 233
CHAPTER X
Tue Elluper $\frac{x^{2}}{a^{3}}+\frac{y^{2}}{b^{3}}=1$
112. Review ..... 238
113. The equation of the tangent to the ellipse $\frac{x^{2}}{a^{2}}+\frac{y^{2}}{b^{4}}=1$ in terms of its slope ..... 238
116. The sum of the focal distaners of any pwint on an ellipse is constant; it is equal to the major axis ..... 230
AตTा 3 PAGE
148. Conatruction of the ellipue ..... 240
113. Auxiliary circles. Eccentric angle ..... 242
10i. The subtangent and subnormal. Construction of tangent and normal ..... 244
14. The tangent and normal lisect externally and internally, rospectively, the angles between the focal radii of the point of contact ..... 246
149. The intersection of the tangents at the extremity of a focal chord ..... 247
150. The locus of the foot of the perpendicular from a focus upon a tangent to an ellipse ..... 248
151. The leves of the intersection of two perpendicular tangents to the ellipme ..... 249
15. Diamoters ..... 250
153. Conjugate diameters ..... 252
154. Given an extremity of a diameter, to find the extremity of its conjugate diameter ..... 253
155. Properties of comjugate diameters of the ellipse ..... 254
158. Eijui-conjugate diameters ..... 257
157. Supplemental chords ..... 259
1is. Equation of the ellipse referred to a pair of conjugate diam- eters ..... 260
159. Ellipwe referred to conjugate diameters; second method ..... 261
CHAPTER XI
Tue Hyperbola $\frac{x^{2}}{a^{2}}-\frac{y^{2}}{b^{2}}=1$
100. Review ..... 265
161. The difference between the focal distances of any point on an hypwriola is constant; it is equal to the transverse axis ..... 266
162. Construction of the hyperbola ..... 267
163. The tangent and normal lisect internally and externally the angles belween the focal radii of the point of contact . ..... 268
161. Conjugate hyperboles ..... 270
105. Asymptotes ..... 272
188. Relation letween conjugate hyperbolas and their asymptotes ..... 275
16\%. Equilateral or rectangular hyperbola ..... 277
108. The byperbola referred to its asymptotes ..... 278
100. The tangent to the hyperkola $r y=c^{2}$ ..... 280
150. Geometric properties of the liyperbola ..... 281
antule pase
171. Diameters. ..... 254
172. Properties of eonjugate diamolorin of the hyperinola ..... $25:$
173. Supplemental chords ..... 257
174. Equations reprenenting an hyperlmola, hut isvolving only une variable ..... 285
CHAPTER XII
Ceneral. Equatios of tire Secusio Degreve
$A x^{2}+2 I I x y+I y^{2}+2(i x+2 F y+C=0$
1is. Cieneral equation of the mecond degree in two sariablen ..... 202
176. Illustrative examuples ..... 294
177. Test for the aquecies of a conie ..... 297
1\%8. Center of a conic section ..... 298
179. Transformation of the equation of as conie to paralled axes through its center. ..... 289
18). The invariants $A+B$ and $I^{3}-A / B$ ..... 301
181. To reduce to its simplest standard form the general equation of a conio ..... 303
182. Summary ..... 306
183. The equation of a conic through given points ..... 307
CIIAPTER XIII
Hieher Plane Curves
184. Definitions ..... 809
I. Algebraic Curves
185. The cissoid of Diocles ..... 809

## ANALYTIC GEOMETRY

## PART I

## CHAPTER I

## INTRODUCTION

## ALGEBRAIC AND TRIGONOMETRIC CONCEPTIONS

1. Number. A number is most simply interpreted as expressing the measurement of one quantity by another quantity of the same kind first chosen as a unit of measure; it is positive, or + , if the measuring unit is taken in the same sense as the thing measured; and negative, or - , if this measuring unit is taken in the opposite sense.
E.g., the unit dollar may be regarded as a dollar of assets, or as a dollar of liabilities; if it is regarded as a dollar of assets, then assets measured by it produce positive numbers, while liabilities measured by it produce negative numbers.

The above definition is consistent with the one usually given; viz. that numbers are positive or negative according as they are greater or less than zero.

If the operations of addition, subtraction, multiplication, division, raising to integer powers, extracting roots, or any combination of these operations, are performed upon given numbers, the result in every case is a number ; it is imaginary
if it involves in any way whatever an indicated even root of a negative number; otherwise it is real.

Every imaginary number may be reduced to the form $a+b \sqrt{-1}$, where $a$ and $b$ are real, and $b \neq 0$.
2. Constants and variables. If $A B$ and $A C$ are two given
 straight lines making an angle $\alpha$ at the point $A$, and if any two points $X$ and $Y$, on these lines, respectively, are joined by a straight line, then

Area of triangle $A X Y=\frac{1}{2} \cdot A X \cdot A Y \cdot \sin \alpha$,
i.e.,

$$
\Delta=\frac{1}{2} \cdot x \cdot y \cdot \sin \alpha,
$$

where $x$ is the length of $A X, y$ is the length of $A Y$, and $\Delta$ is the area of the triangle.

If now the points $X$ and $Y$ are moved along the lines $A B$ and $A C$ in any way whatever, then $\Delta, x$, and $y$ will each pass through a series of different values, -they are variable numbers or variables; while $\frac{1}{2}$ and $\sin \alpha$ will remain unchanged,-they are constant numbers or constants.

It is to be remarked that $\frac{1}{2}$ has the same value wherever it occurs, - it is an absolute constant; while $\alpha$, though constant for this series of triangles, may have a different constant value for another series of triangles, 一it is an arbitrary constant.

Because $x$ and $y$ may separately take any values whatever they are independent variables; while $\Delta$, whose value depends upon the values of $x$ and $y$, is a dependent variable.
The illustrations just given may serve to give a clearer conception of the following more formal definitions.

An absolute constant is a number which has the same value wherever it occurs; such are the numbers $2,7, \frac{3}{6}, 6, \pi, e$
(where $\pi=3.14159265 \ldots$, approximately 22 , the ratio of the circumference of a circle to its diameter; and

$$
\theta=2.71828182 \ldots=1+\frac{1}{1}+\frac{1}{2}+\frac{1}{13}+\cdots,
$$

approximately fo the base of the Naperian system of logarithms).

An arbitrary constant is a number which retains the same value throughout the investigation of a given problem, but may have a different fixed value in another problem.

An independent variable is a number that may take any value whatever within limits prescribed by the conditions of the problem under consideration.

A dependent variable is a number that depends for its value upon the values assumed by one or more independent variables.*

A number that is greater than any assignable number, however great, is an infinite number; one that varies and becomes and remains smaller (numerically, not merely algebraically leas) than any assigned number, however small, is an infinitesimal number. All other numbers are finite.
3. Functions. A number so related to one or more other numbers that it depends upon these for its value, and takes in general a definite value, or a finite number of definite values, when each of these other numbers takes a definite value, is a function of these other numbers. E.g., the circumference and the area of a circle are functions of its radius; the distance traveled by a railway train is a function of its time and rate; if $y=3 x^{3}+52-8$, then $y$ is a function of $x$.

[^0]4. Identity, equation, and root. If two functions involving the same variables are equal to each other for all values of those variables they are identically equal. Such an equality is expressed by writing the sign $\equiv$ between the two functions, and the expression so formed is an identity. If, on the other hand, the two functions are equal to each other only for particular values of the variables, the equality is expressed by writing the sign $=$ between the two functions, and the expression so formed is an equation. The particular values for which the two functions are equal, i.e., those values of the variables which satisfy the equation, are the roots of the equation.
\[

$$
\begin{aligned}
& \text { E.g. }(x+y)^{2} \equiv x^{2}+2 x y+y^{2},(x+a)(x-a)+a^{2} \equiv x^{2}, \\
& \text { and } \quad x+\frac{3}{x-1} \equiv \frac{x^{2}-x+3}{x-1}
\end{aligned}
$$
\]

are identities ; while $3 x^{2}-10 x+2=2 x^{2}-4 x-6$, or, what is the same thing, $x^{2}-6 x+8=0$, is an equation. The roots of this equation are the numbers 2 and 4.

Special attention is called to the fact that an equation always imposes a condition.
E.g. $x^{2}-6 x+8=0$ if, and only if, $x=2$ or $x=4$. So also the equation $a x+b y+c=0$ imposes the condition that $x$ shall be equal to

$$
\frac{-b y-c}{a}
$$

5. Functions classified. A functional relation is usually expressed by means of an equation involving the related numbers. If the form of this equation is such that one of the variables is expressed directly in terms of the others, then that variable is called an explicit function of the others; if it is not so expressed, it is an implicit function.
E.g., the equations $y=\sqrt{5-x^{2}}, x^{2}+y^{2}=5$, and $x=\sqrt{5-y^{2}}$ express the same relation between $x$ and $y$; in the first $y$ is an explicit function
of $x$, in the second each bs an implieit function of the other, white in the third $x$ is an explicat function of $y$.

The wort "function" is, for brevity, usually represented by a single letter, such as $f, F, \phi, \psi, \cdots ;$ thus $y=\phi(x)$ means that $y$ is a function of the indepentent variable $x$, and is read " $y$ equals the $\phi$-function of $x$ "; so also $z=\boldsymbol{P}(u, v, x)$ means that $z$ is a function of the independent variables $u_{0} v_{0}$ and $x$, and it is read, " $z$ equals the $F$-function of $u, v$, and $x_{0}$ "

A function is algebraic if it involves, so far as the independent variables are concerned, only a finite number of the operations of addition, subtraction, multiplication, division, raising to integer powers, and extracting roots. All other functions are transcendental.
E.g. $2 x^{0}-5 x-17, x y+y^{3}-7 x$, and $\frac{2 x^{3}-11 y^{2}}{x+x y-7 y^{2}}$ are algebraio functions; while $2^{2}, a^{*}, \sin x, \tan ^{-1} 2$, and $\log t$ are transcendental functions.
6. Notation. In general, absolute constants are represented by the Arabic numerals, while arbitrary constants and variables are represented by letters. A few absolate constants are, however, by general consent, represented by letters; examples of such constants are $\pi$ and e (Art. 2). Variables are usually represented by the last letters of the alphabet, such as $u, v, v, x, y, z$; while the first letters, $a, b, c, \cdots$ are reserved to represent constants.

Particular fixed values from among those that a variable may assume are sometimes in question; e.g., the values, $x=2$ and $x=-1$, for which the function $x^{2}-x-2$ vanishes; such values may conveniently be denoted by affixing a subsoript to the letter representing the variable. Thus $x_{1}, x_{3}, x_{3}, \ldots$ will he used to denote particular values of the variable $x$.

Similarly, variables which enter a problem in analogous
ways are usually denoted by a single letter having accents attached to it ; thus $x^{\prime}, x^{\prime \prime}, x^{\prime \prime \prime}, \cdots$ denote variables that are similarly involved in a given problem.
Again, each of the two equations, $y=3 x^{2}-4 x+10$ and $y=\phi(x)$, asserts that $y$ is a function of $x$; but while the former tells precisely how $y$ depends upon $x$, the latter merely asserts that there is such a dependence, without giving any information concerning the form of that dependence. If several different forms of functions present themselves in the same problem, they are represented by different letters, each letter representing a particular form for that problem, though it may be chosen to represent an entirely different form in another problem.
E.g., if the form of $\phi$, in a given problem, is defined by the equation

$$
\phi(x)=\frac{3 x^{5}-x^{4}+5}{2 x+1}
$$

then, in the same problem,

$$
\phi(v)=\frac{3 v^{6}-v^{4}+5}{2 v+1}, \quad \phi(1)=\frac{7}{3}, \quad \text { and } \quad \phi(0)=5 .
$$

7. Continuous and discontinuous functions. In general a function takes different values when different values are assigned to its independent variable. If $y=\phi(x)$, then, for $x=a$ and $x=b$, the function becomes $y_{1}=\phi(a)$ and $y_{2}=\phi(b)$, and $y_{1}$ is in general different from $y_{2}$. The function $\phi(x)$ is said to be a continuous function of $x$ between $x=a$ and $x=b$, if, while $x$ is made to pass successively through all real values from $a$ to $b, y$ remains real and finite and passes correspondingly through all values from $y_{1}$ to $y_{2}$.

This definition may be more precisely stated, thus: If $x_{1}$ and $x_{2}$ are any real values of $z$ which lie hetween the values $a$ and $b$, and if the corresponding values of $y$, viz. $\phi\left(x_{1}\right)$ and $\phi\left(x_{2}\right)$, are real and finite; and if
a powitive number y can be found, such that by taking numerically

$$
x_{1}-x_{1}<\eta
$$

it will follow that, numerically,

$$
\phi\left(x_{1}\right)-\phi\left(x_{2}\right)<e
$$

where $\varepsilon$ is any awsigned positive number, however amall; then $\phi(x)$ is a continuous function of $a$ for values from a to $b$.

Or, in words: $y$ is a continuous function of $x$ for all values of $z$ in tho interval from a to b. it, by taking any two values of $a$ in the interval sufficiently near together, the difference bet ween the corresponding valuma of $y$ can be made less than any assigned number, however small.

A discontinuous function is one that does not fulfil the conditions for continuity. It is, however, usually discontinuous for only a limited number of particular values of its independent variable, while between these values it is continuous.

As familiar examples of continuous functions may be mentioned: the length of a solar shadow; the area of a cross-section of a growing tree, or of a growing peach; tho height of the mercury in a barometer ; the temperature of a room at varying distances from the source of heat; and interest as a function of time.

So, also, $y=3 x^{2}+4 x+1$ is a continuous function of $x$ for all finite values of $x$.

For, $y$ remains real and finite so long as $x$ remains real and finite, and, if $x_{1}$ and $x_{2}$ be any two finite values of $x$ which differ from each other by $\eta$, i.e., if $x_{3}=x_{1} \pm \eta$, then

$$
\begin{aligned}
y_{2}-y_{1} & =3 x_{3}^{2}+4 x_{2}+1-\left(3 x_{1}^{2}+4 x_{1}+1\right) \\
& =3\left(x_{1} \pm \eta\right)^{2}+4\left(x_{1} \pm \eta\right)+1-\left(3 x_{1}^{2}+4 x_{1}+1\right) \\
& = \pm\left(6 x_{1}+4+3 \eta\right) \eta
\end{aligned}
$$

Now to show that $y=3 x^{2}+4 x+1$ is contimuous for $x=x_{1}$, it only remains to show that, by taking $\eta$ sufficiently
small, i.e., by taking $x_{3}$ sufficiently near $x_{1}, y_{3}$ can be made to differ from $y_{1}$ by less than any assigned number ( $\epsilon$ ), however small. But this is evident; for $\eta$ may be taken as near zero as desired, hence the factor $6 x_{1}+4+3 \eta$ as near $6 x_{1}+4$ as desired, and the product therefore as near zero as is neeessary to be less than e.

On the other hand, if, at regular intervals of time, apples are dropped into a basket, the combined weight of the basket and apples will increase discontinuously; i.e., their total weight is a discontinuous function of the time.

## EXERCISES

1. If $A x+B y+C=0$, prove that $y$ is a continuous function of $x$; and $x$, of $y$.
2. If $x^{2}+y^{2}-4=0$, prove that $y$ is a continuous function of $x$, when $2>x>-2$.
3. If $\frac{x^{2}}{a^{2}}+\frac{y^{2}}{b^{2}}=1$, prove that $x$ is a continuous function of $y$, when $b>y>-b$.
4. If $\frac{x^{2}}{a^{2}}-\frac{y^{2}}{b^{2}}-1=0$, is $x$ a continuous function of $y$ ?
5. If $s t-9=0$, is $s$ a continuous function of $t$ ?
6. If $u^{2}-3 v=0$, is $u$ a continuous function of $v$ ? Is $v$ a continuous function of $u$ ?
7. Show that all functions of the form

$$
a_{0} x^{n}+a_{1} x^{n-1}+a_{2} x^{n-2}+\cdots+a_{n-1} x+a_{n}
$$

$w$ here $a_{0} a_{v}, a_{2} \cdots a_{n}$ are constants, are continuous for all finite values of $z$.
B. If $\frac{y-1}{y-2}=5^{\frac{1}{2-1}}$, show that $y$ is discontinuous for $x=1$.
9. Find the value of $x$ for which $y_{1}=c \frac{\frac{1}{e^{x-0}}-1}{e^{\frac{1}{x-s}}+1}$, is discontinuous.
10. Interest on moncy lianed is calculated by the formula

$$
I=P \cdot R \cdot T .
$$

Is the interest $(I)$ a continuous or a dincontinuous function of $P$ ? of $\Omega$ ? of $T$ ?
8. The present work will be concerned for the most part with algebraie functions involving only the first and seoond powers of the variable, i.e., with algebraic equations of the first and second degree. A review is therefore given of the solution and theory of the quadratie equation, presenting in brief the most important results which will be needed in the Analytic Geometry. The student should become thoroughly familiar with this theory, as well as with the review of the trigonometry which fullows it.
9. The quadratic equation. Its solution. The most general equation of the second degree, in one unknown number, may be written in the form

$$
\begin{equation*}
a x^{2}+b x+e=0 \tag{1}
\end{equation*}
$$

where $a, b$, and $e$ are known numbers. This equation may be solved by the method of "completing the square," which gives

$$
\begin{equation*}
x^{2}+\frac{b}{a} x+\left(\frac{b}{2 a}\right)^{2}=\left(\frac{b}{2 a}\right)^{2}-\frac{c}{a}, \tag{2}
\end{equation*}
$$

i.e., $x+\frac{b}{2 a}= \pm \sqrt{\left(\frac{b}{2 a}\right)^{2}-\frac{c}{a}}= \pm \frac{1}{2 a} \sqrt{b^{2}-\operatorname{tac}}$,
whence

$$
\begin{equation*}
x=-\frac{b}{2 a} \pm \frac{1}{2 a} \sqrt{b^{2}-4 a c} . \tag{3}
\end{equation*}
$$

If $x_{1}$ and $x_{3}$ are used to denote the roots of eq. (1), they may be written

$$
\begin{equation*}
x_{1}=\frac{-b+\sqrt{b^{2}-4 a c}}{2 a} \text { and } x_{2}=\frac{-b-\sqrt{b^{2}-4 a c}}{2 a} \cdots \tag{5}
\end{equation*}
$$

The nature of the roots (5) depends upon the number under the radical sign, i.e., upon $b^{2}-4 a c$, giving three cases to be considered, viz.:
if $b^{2}-4 a c>0$, then the roots are both real and unequal,
if $b^{2}-4 a c=0$, then the roots are both real and equal,
if $b^{2}-4 a c<0$, then the roots are both imaginary.
Thus the character of the roots of a given quadratic equation may be determined without actually solving the equation, by merely calculating the value of the expression $b^{2}-4 a c$. This important expression is called the discriminant of the quadratic equation; when equated to zero it states the condition that must hold among the coefficients if the equation has equal roots.

## EXERCISES

1. Show which of the following equalities are identities:
(1) $x^{2}-4 x+4=0$;
(4) $(p+q)^{2}=p^{3}+q^{8}+3 p q(p+q)$;
(2) $(s+t)(s-t)=s^{2}-t^{2}$;
(5) $x^{2}+5 x+6=(x+3)(x+2)$.
(3) $\frac{a^{8}+\beta^{a}}{a+\beta}=a^{2}-\alpha \beta+\beta^{\text {s }}$;
2. Determine, without solving the equation, the nature of the roots of

$$
3 x^{2}+8 x+1=0
$$

Solutios. Since $b^{2}-4 a c=64-12=52$, i.e., is positive, therefore the roots are real and unequal; again, since $a, b$, and $c$ are all positive, therefore both roots are negative (ef. eq. (4), Art. 9 ).
3. Without solving the equation, determine the character of the roots of $8 x^{2}-3 x+1=0$.
4. Given the equation $x^{2}-3 x-m\left(x+2 x^{2}+4\right)=5 x^{2}+3$. Find the roots. For what values of $m$ are these roots equal?
5. Determine, without solving, the character of the roots of the equations:

$$
\text { (1) } 5 z^{2}-2 z+5=0 ; \text { (2) } x^{2}+7=0 \text {; (3) } 3 t^{2}-t=19
$$

6. Determine the ralues of $m$ for which the follow ing equations alasil have equal roots:
(1) $x^{3}-2 x(1+3 m)+7(3+2 m)=0$;
(2) $m x^{3}+2 x^{2}-2 m=3 m x-9 z+10$;
(3) $4 x^{2}+(1+m) z+1=0$;
(4) $x^{2}+(6 x+m)^{2}=a^{2}$.
7. If in the equation $2 a x(a x+n c)+\left(n^{2}-2\right) c^{2}=0, x$ is real, nhow that $n$ is not greater, in absolute value, than 2.
8. If $x$ is real in the equation $\frac{x}{x^{3}-5 x+19}=a$, show that $a$ is not greater tham l , nor leas than -
9. For what values of $e$ will the following equations have equal roote ?
(1) $3 x^{2}+4 x+c=0$;
(2) $(m s+c)^{2}=1 / x ;$
(3) $4 x^{2}+0(2 x+c)^{2}=36$.
10. Solve the equations in examples 2,3 , and 5 .
11. Solve the equations:
(1) $x^{4}-25 x^{3}=-144$;
(2) $\frac{3 x-2}{x-2}-\frac{2 x+1}{x+2}+\frac{12}{x^{2}-4}=0$
12. Zero and infinite roots. In the following pages it will sometimes be necessary to know the conditions among the coeflicients of a quadratic equation that will make one or both of its roots zero, or the conditions that will make one or both of the roots infinitely large. In equations (5) of Art. 9, $x_{1}$ and $x_{2}$, i.e. the roots of $a x^{3}+b x+c=0$, were found; and it is at once seen that
$x_{1}=\frac{-b+\sqrt{b^{2}-1+c}}{2 a}$

$$
\begin{equation*}
=\frac{-b+\sqrt{b^{2}-4 a c}}{2 a} \frac{-b-\sqrt{b^{2}-4 a c}}{-b-\sqrt{b^{2}-4 a c}}=\frac{2 c}{-b-\sqrt{b^{2}-4 a c}} \tag{1}
\end{equation*}
$$

and that

$$
\begin{equation*}
x_{2}=\frac{-b-\sqrt{b^{2}-4 a c}}{2 a}=\frac{2 c}{-b+\sqrt{b^{2}-4 a c}} \tag{2}
\end{equation*}
$$

Equations (1) and (2) show that :
(1) If $a$ and $b$ remain unchanged while $e$ grows smaller,
then $x_{1}$ grows smaller and $x_{2}$ grows larger ; and if $c \doteq 0$,* then $x_{1} \doteq 0$, while $x_{2} \doteq-\frac{b}{a}$.
(2) If a remains unchanged while $c \doteq 0$ and $b \doteq 0$, then $x_{1} \doteq 0$ and $x_{2} \doteq 0$.
(3) If $b$ and $c$ remain unchanged while $a \doteq 0$, then $x_{1} \doteq-\frac{c}{b}$ and $x_{2}$ becomes infinitely large.
(4) If e remains unchanged while $a \doteq 0$ and $b \doteq 0$, then both $x_{1}$ and $x_{2}$ become infinitely large.
(5) If $a$ and $c$ remain unchanged while $b \doteq 0$, then $x_{1} \doteq \sqrt{\frac{-c}{a}}$ and $x_{3} \doteq-\sqrt{\frac{-c}{a}}$.

The student should translate (1), (2), (3), (4), and (5) into more general terms by reading "the absolute term approaches zero as a limit" instead of " $c \doteq 0$," etc.
11. Properties of the quadratic equation. By adding the two roots of

$$
\begin{equation*}
a x^{2}+b x+c=0 \tag{1}
\end{equation*}
$$

and also multiplying them together, the relations

$$
\begin{equation*}
x_{1}+x_{2}=-\frac{b}{a} \text { and } x_{1} x_{2}=\frac{c}{a} \tag{2}
\end{equation*}
$$

are obtained; or, if equation (1) is written with the coefficient of the term of the second degree reduced to unity, as

$$
\begin{equation*}
x^{2}+p x+q=0 \tag{3}
\end{equation*}
$$

these relations become

$$
\begin{equation*}
x_{1}+x_{2}=-p \text { and } x_{1} x_{2}=q \tag{4}
\end{equation*}
$$

Or, expressed in words: the coefficient of the term of the second degree being unity, the coefficient of the term of

[^1]the first degree is the negative of the sum of the roots, while the term free from $x$ is the product of the roots.

1f, therefore, the roots of a quadratic equation are not themselves needed, but only their sum or product is dosired, these may be obtained directly from the given equation by inspection.
E.g., the half sum of the roots of the equation
is

$$
\begin{gathered}
m^{2} x^{2}+2(b m-2 l) x+83=0 \\
\frac{x_{1}+x_{3}}{2}=-\frac{2(6 m-2 l)}{2 m^{2}}=\frac{2 l-6 m}{m^{2}}
\end{gathered}
$$

Moreover, if $x_{1}$ and $x_{2}$ are the roots of the equation

$$
x^{2}+p x+q=0
$$

then $x-x_{1}$ and $x-x_{2}$ are the factors of its first member.
For, by equation (t) above, this equation may be writuen
and

$$
x^{3}+p x+q \equiv x^{2}-\left(x_{1}+x_{2}\right) x+x_{1} x_{2}=0,
$$

hence

$$
\begin{gathered}
x^{2}-\left(x_{1}+x_{2}\right) x+x_{1} x_{2}=\left(x-x_{1}\right)\left(x-x_{2}\right), \\
x^{2}+p x+q=\left(x-x_{1}\right)\left(x-x_{2}\right) .
\end{gathered}
$$

Conversely: if a qualratic function can be separated into two factors of the first degree, then the roots can be immedately written by inspection.

For, if $x^{2}+p x+q=\left(x-x_{1}\right)\left(x-x_{2}\right)$, then the first member will vanish if, and only if, $x-x_{1}=0$ or $x-x_{3}=0$; i.e. $x^{2}+p x+q=0$ if $x=x_{1}$ or $x=x_{2}$, hence $x_{1}$ and $x_{2}$ are the roots of the equation $x^{2}+p x+q=0$ (cf. Art. 4).
12. The quadratic equation involving two unknowns. One cquation involving two unknown numbers cannot the solved uniquely for the values of those numbers which satisfy the equation; but if there is assigned to cither of those num-
bers a definite value, then at least one definite and corresponding value can be found for the other, so that, this pair of values being substituted for the unknown numbers, the equation will be satisfied. In this fray an infinite number of pairs of values, that will satisfy the equation, may be found.

If, however, the equation is homogeneous in the two unknowns, i.e., of the form

$$
a x^{2}+b x y+c y^{2}=0
$$

then the ratio $x: y$ may be regarded as a single number, and the equation has properties precisely like those discussed in Arts. 9, 10, and 11.

To solve a system consisting of two or more independent simultaneous equations, involving as many unknown elements, it is necessary to combine the equations so as to eliminate all but one of the unknown elements, then to solve the resulting equation for that one, and, by means of the roots thus obtained, find the entire system of roots.

## EXERCISES

1. Given the equation $x^{2}+3 x-4+m\left(3 x^{2}-4\right)-2 m x^{2}=0$, find the sum of the roots; the product of the roots; also the factors of the first member.
2. Factor the following expressions:
(1) $x^{2}-5 x+4$;
(3) $m x^{2}-3 x+c$;
(5) $3 w^{\frac{5}{3}}-94 w^{\frac{5}{8}}-64$;
(2) $x^{2}+2 x-8$;
(4) $a x^{2}+b x y+c y^{2}$;
(6) $11-27 y-18 y^{2}$.
3. Without first solving the equation

$$
x^{2}-3 x-m\left(x+2 x^{2}+4\right)=5 x^{2}+3
$$

find the sum, and the product, of its roots. For what value of $m$ are its roots equal? For what value of $m$ does one root become infinitely large? If all the terms are transposed to one member, what are the factors of that member?
4. Without first solving, determine the nature of the roots of the equation $(m-2)(\log x)^{2}-(2 m+3) \log x-4 m=0$. [Regard $\log x$ as the unknown element.]

For whint values of mare the rowts equal? Roal? One infintiely groat? One moto? Find the facturn of the firnt member of then egquation.
5. Find five pairs of numbers that atiafy the equation:
(1) $x+3 y-7=0 ;$
(3) $y^{2}=16 x ;$
(2) $x^{4}+y^{3}=4$;
(1) $3 x+63 y-8 y^{2}+3 x^{3}=0$.
6. Without solving, detormine the nature of the rools of the equation:

$$
9 x^{2}+12 x y+4 y^{3}=0,3 u^{2}-u x+19 u^{3}=0
$$

7. Solve the following pains of simultaneons equations :
(1) $3 x-5 y+2=0$, and $2 x+7 y-4=0$;
(2) $5 y+2 z+3=0$, and $7 y+4 z+2=0$;
(8) $y-3 x+c=0$, and $y^{2}=9 x$;
(4) $x^{2}+y^{2}=5$, and $y^{2}=6 x$;
(5) $b^{3} x^{3}+a^{3} y^{3}=a^{2} b^{2}$, and $y=a x+b ;$
(8) $\frac{x^{2}}{10}+\frac{y^{2}}{9}=1$, and $\frac{x^{2}}{10}-\frac{y^{2}}{9}=1$.
B. Inetermine those values of $b$ for which each of the following pairs of equations will be satistied by two equal values of $y$ :
(1) $\left\{x^{3}+y^{2}=u^{2}, y=6 x+b\right\} ;$
(2) $\left\{y=m x+b, y^{2}=\{x\} ;\right.$
(3) $\left\{3 y+2 x=b, 6 x^{2}+y^{2}=12\right\}$.
8. Determine, for the pairs of equations in Ex. 8, those values of 8 which will give equal values of $x$.

## TRIGONOMETRIC CONCEPTIONS AND FORMULAS

13. Directed lines. Angles. A line is said to be directed when a distinetion is mado between the segment from any point $A$ of the line to another point $B$, and the opposite segment from $\boldsymbol{B}$ to $A$. One of these directions is chosen as positive, or + , and the opposite direction is then negative or -.

The angle formed by two intersecting directed straight lines is that relation between the positions of the two lines which is expressed by the amount of rotation about their point of intersection necessary to bring the pisitive end
of the initial side into coincidence with the positive end of the terminal side. The point in which the lines intersect is called the vertex of the angle. The angle is prositive, or + , if the rotation from the initial to the terminal side is in counter-clockuise direction; the angle is negative, or - , if the rotation is clockuise.

The angle formed by two directed straight lines in space, which do not meet, is equal to the angle between two intersecting lines, which are respectively parallel to the given lines.

For the measurement of angles there are two absolute units :
(1) The angular magnitude about a point in a plane, i.e., a complete revolution. One fourth of a complete revolution is called a right angle, $\frac{1}{90}$ of a right angle is a degree $\left(1^{\circ}\right)$, $\frac{6}{6}^{2}$ of a degree is a minute $\left(1^{\prime}\right)$, and $\frac{1}{60}$ of a minute is a second ( $1^{\prime \prime}$ );
$(-)$ the angle whose subtending circular arc is equal in length to the radius of that are; this angle is called a radian $\left\{1^{(r)}\right\}$; it is independent of the length of the radius. Since $\frac{\text { circumference }}{\text { diameter }}=\frac{\text { semi-circumference }}{\text { radius }}=\pi$, it follows that the angle formed by a half rotation, i.e., $180^{\circ}$, is $\pi$ radians; i.e.,

$$
180^{\circ}=\pi^{(r)}=\left(\frac{22}{7}\right)^{(r)} \text { approximately } ;
$$

also $\quad 1^{(r)}=\frac{180^{\circ}}{\pi}=57^{\circ} 17^{\prime} 44.8^{\prime \prime}$ approximately.
A right angle is $90^{\circ}$ or $\left(\frac{\pi}{2}\right)^{(r)}$.
When there is no danger of being misunderstood, the index $(r)$ is omitted, and $\frac{\pi}{2}$ radians is written simply as $\frac{\pi}{2}$, and $\operatorname{not}\left(\frac{\pi}{2}\right)^{(r)}$.
14. Trigonometric ratios. If from any point $P$ in the terminal side of an angle $\theta$, at a distance $r$ from the vertex, a perpendicular MP is drawn to the initial side meeting it in

$M$, and if $M P$ the represented by $y$ and $V M$ by $x$, then, by general agreement, $y$ is + if $M P$ makes a positive right angle with the initial line, and - if this right angle is negative ; similarly, $x$ is + if $V M$ extends in the positive direction of the initial line, and - if it extends in the opposite direction.

The three numbers $r, x$, and $y$ form with each other six ratios; these ratios, moreover, depend for their value solely upon the size of the angle $\theta$, and not at all upon the value of r. These six ratios are known as the trigonometric ratios or functions of the angle $\theta$, and are named as follows :

$$
\begin{array}{lll}
\text { sine } \theta=\frac{y}{r}, & \text { tangent } \theta=\frac{y}{x}, & \text { secant } \theta=\frac{r}{x}, \\
\text { cosine } \theta=\frac{x}{r}, & \text { cotangent } \theta=\frac{x}{y}, & \text { cosecant } \theta=\frac{r}{y} .
\end{array}
$$

The abbreviated symbols for these functions are $\sin \theta$, $\cos \theta, \tan \theta, \cot \theta, \sec \theta$, and $\csc \theta$, respectively. The funetions are not all independent, but are connected by the following relations:
(1) $\sin \theta \cdot \cos \theta=1$,
(5) ent $\theta=\cos \theta: \sin \theta$,
(2) $\cos \theta \cdot \sec \theta=1$,
(6) $\sin ^{2} \theta+\cos ^{2} \theta=1$,
(3) $\tan \theta \cdot \cot \theta=1$,
(i) $\tan ^{2} \theta+1=\sec ^{2} \theta$,
(4) $\tan \theta=\sin \theta: \cos \theta$,
(8) $\cot ^{2} \theta+1=\csc ^{2} \theta$.
$13 y$ means of these eight relations all the trigonometric functions of any angle may be expressed in terms of any given function. E.g., suppose the sine of an angle is given, and the tangent of this angle, in terms of the sine, is wanted:

$$
\begin{equation*}
\tan \theta=\frac{\sin \theta}{\cos \theta} \tag{t}
\end{equation*}
$$

and by (6),
hence

$$
\begin{aligned}
& \cos \theta=\sqrt{1-\sin ^{2} \theta} \\
& \tan \theta=\frac{\sin \theta}{\sqrt{1-\sin ^{2} \theta}}
\end{aligned}
$$

If the numerical value of $\sin \theta$ is given, this last formula gives the corresponding numerical value of $\tan \theta ;$ e.g., if $\sin \theta=\frac{3}{6}$, then

$$
\tan \theta=\frac{\frac{3}{6}}{\sqrt{1-\left(\frac{3}{b}\right)^{2}}}= \pm \frac{3}{4}
$$

15. Functions of related angles. Based upon the definitions of the trigonometric functions the following relations are readily established.

If $\theta$ is any plane angle, then*

$$
\begin{array}{ll}
\sin (-\theta)=-\sin \theta, & \cos (-\theta)=+\cos \theta \\
\tan (-\theta)=-\tan \theta, & \csc (-\theta)=-\csc \theta \\
\sec (-\theta)=+\sec \theta, & \cot (-\theta)=-\cot \theta \tag{1}
\end{array}
$$

(2) $\sin (\pi \pm \theta)=\mp \sin \theta, \quad \cos (\pi \pm \theta)=-\cos \theta$, $\tan (\pi \pm \theta)= \pm \tan \theta, \quad \csc (\pi \pm \theta)=\mp \csc \theta$,
$\sec (\pi \pm \theta)=-\sec \theta, \quad \cot (\pi \pm \theta)= \pm \cot \theta ;$
(3) $\sin \left(\frac{\pi}{2} \pm \theta\right)=+\cos \theta, \quad \cos \left(\frac{\pi}{2} \pm \theta\right)=\mp \sin \theta$,

$$
\begin{array}{ll}
\tan \left(\frac{\pi}{2} \pm \theta\right)=\mp \cot \theta, & \csc \left(\frac{\pi}{2} \pm \theta\right)=+\sec \theta \\
\sec \left(\frac{\pi}{2} \pm \theta\right)=\mp \csc \theta, & \cot \left(\frac{\pi}{2} \pm \theta\right)=\mp \tan \theta
\end{array}
$$

- The student should thoroughly familiarize himself with these formulas, and those of Art. 10, as well as with the derivation of each.

16. Other important formulas. If $\theta_{1}$ and $\theta_{2}$ are any two plane angles, then

$$
\begin{aligned}
& \sin \left(\theta_{1} \pm \theta_{2}\right)=\sin \theta_{1} \cos \theta_{3} \pm \cos \theta_{1} \sin \theta_{2} \\
& \cos \left(\theta_{1} \pm \theta_{2}\right)=\cos \theta_{1} \cos \theta_{3} \mp \sin \theta_{1} \sin \theta_{2} \\
& \tan \left(\theta_{1} \pm \theta_{2}\right)=\frac{\tan \theta_{1} \pm \tan \theta_{2}}{1 \mp \tan \theta_{1} \tan \theta_{3}} .
\end{aligned}
$$

If $\theta$ is any plane angle, then

$$
\begin{aligned}
\sin 2 \theta & =2 \sin \theta \cos \theta, \\
\cos 2 \theta & =\cos ^{2} \theta-\sin ^{2} \theta=1-2 \sin ^{2} \theta=2 \cos ^{2} \theta-1, \\
\tan 2 \theta & =\frac{2 \tan \theta}{1-\tan ^{2} \theta} \\
\sin \frac{\theta}{2} & =\sqrt{1(1-\cos \theta)}, \\
\cos \frac{\theta}{2} & =\sqrt{\frac{1}{2}(1+\cos \theta)}, \\
\tan \frac{\theta}{2} & =\sqrt{\frac{1-\cos \theta}{1+\cos \theta}}=\frac{1-\cos \theta}{\sin \theta}=\frac{\sin \theta}{1+\cos \theta} .
\end{aligned}
$$

If $a, b$, and $c$ are the sides of a triangle lying respeotively opposite the angles $\boldsymbol{A}, \boldsymbol{B}$, and $\boldsymbol{C}$, and if $\Delta$ is the area of this triangle, then

$$
a^{2}=b^{2}+c^{2}-2 b c \cos A, \text { and } \Delta=\frac{1}{2} b c \sin A .
$$

## EXERCISES

1. Express in radinus the angles:
$15 ; 60^{\circ} ; 135^{\circ} ;-252^{\circ} ; ~ \& ~ \mathrm{rt}$. angle; $10^{\circ} 10^{\prime} 10^{\prime \prime} ; 89^{\circ} 2^{\prime} ;(3 \pi)^{\circ}$.
2. Express in degrees, minutes, and seconds, the angles:
$\left(\frac{\pi}{1}\right)^{(n)}:\left(\frac{3 \pi}{3}\right)^{(n)} ;\left(\frac{1}{4}\right)^{(n)}:\left(\frac{2}{8}\right)^{(m)} ; \frac{7}{10}$ of a revolution; $\frac{5}{4}$ rt. angle.
3. Find the values of the other trigonometrie functions, given :
(1) $\tan \theta=3$;
(2) $\sec x=-\sqrt{2}$;
(5) $\cot \psi=\{;$ and (5) $\operatorname{cse} u=-2$.
(3) $\cos \phi=\frac{1}{\sqrt{3}}$;
(t) $\sin t=\$ ;$

Solution of (1). If $\tan \theta=3$, then substituting this value in (3) of Art. 14, gives $\cot \theta=1 ;$ sulnstituting these values in ( 7 ) and ( 8 ) of the same article gives the values of $\sec \theta$ and of $\csc \theta$; and substituting those values in (1) and (2) gives $\sin \theta$ and $\cos \theta$.

Amother method: Construct a right triangle $A B C$ with the sides $A B=1$ and $B C=3$, then $\angle B A C$ is an angle whose tangent is 3 . If $A B=1$ and $B C=3$, then $A C=\sqrt{10}$, and the other func-
 tions of the angle $B . A G$ are at once seen to be:

$$
\begin{gathered}
\sin \theta=\frac{3}{\sqrt{10}}, \quad \cos \theta=\frac{1}{\sqrt{10}}, \quad \csc \theta=\frac{\sqrt{10}}{3} \\
\sec \theta=\sqrt{10}, \text { and } \cot \theta=\frac{1}{3} .
\end{gathered}
$$

Fither of these methods may be employed to solve the other parts of this example; the second method is usually to be preferred.
4. By means of a right triangle, with appropriate acute angles, find the numerical values of the trigonometric ratios of the following angles:

$$
30^{\circ} ; 45^{\circ} ; 60^{\circ} ; 90^{\circ} ; 135^{\circ} ; \text { and }-45^{\circ}
$$

5. Express the following functions in terms of functions of positive angles less than $90^{\circ}$ :
$\tan 3500^{\circ} ;-\csc 290^{\circ} ; \sin \left(-369^{\circ}\right) ;-\cos \frac{11 \pi}{5} ;$ and $\cot \left(-1215^{\circ}\right)$.
6. Solve the following equations:

$$
\begin{gathered}
\text { (1) } \sin \theta=-\cos 210^{\circ} ;(2) \cos \theta=\sin 2 \theta ; \text { (3) } \frac{\cos x}{\sin x \cot ^{2} x}=\sqrt{3} ; \\
\text { and (4) }\left(\sec ^{2} x-1\right)\left(\csc ^{2} x+1\right)=\frac{s}{3}
\end{gathered}
$$

7. In the following identities transform the first member into the necond:
(1) $\frac{\tan \theta-\cot \theta}{\tan \theta+\cot \theta} \equiv \frac{2}{\csc ^{2} \theta}-1$; $\quad$ (2) $\frac{\sec x+\csc x}{\sec x-\csc x} \equiv \frac{1+\cot x}{1-\cot x}$;
(3) $\operatorname{esc} x(\sec x-1)-\cot x(1-\cos x) \equiv \tan x-\sin x$;
(4) $(2 r \sin a \cos a)^{2}+r^{2}\left(\cos ^{2} a-\sin ^{2} a\right)^{2} \equiv r^{2}$;
(5) $(\cos a \cos b+\sin a \sin b)^{2}+(\sin a \cos b-\cos a \sin b)^{2} \equiv 1$; and
(6) $(r \cos \phi)^{2}+(r \sin \phi \cos \theta)^{2}+(r \sin \phi \sin \theta)^{2} \equiv r^{2}$.
8. Orthogonal projection. The orthogonal projection ${ }^{\text {b }}$ of a point upon a line is the fint of the preppenticular from the proint to the line. In the figure, $M$ is the projection of $P$ upoin $A / s$. The projection of a segment $P Q$ of a

line upon another line $A B$. is that part of the second line extending from the projection of the initial point of the segment to the projection of the terminal point of the segment. Thus $M N$ is the projection of $P Q$ upon $A B$, and $N M$ is the prujection of $Q P$ upon $A B$.

The length of the projection can easily be expressed in terms of the length of the segment and the angle which it makes with the line upon which the segment is projected ; for

$$
\begin{aligned}
& \frac{M N}{P Q}=\frac{P H}{P Q}=\cos a \\
\therefore \quad & M N=P Q \cdot \cos a ;
\end{aligned}
$$

i.e., the projection of a segment of a line upon another line is ryual to the product of its length by the cosine of the angle which it makes with that other line.

A line made up of parts $P Q, Q R, R S, \cdots$ (Fig. ia, rib), which are straight lines having different directions, is a broken line: and the projection of a broken line upon any line is the algebraie sum of the projections of its parts upon the same

[^2]line. Thus the projection of $P Q R S T$ upon $A B$ is the projection of $P Q+$ the projection of $Q R+\cdots$, upon $A B$; i.e., proj. $P Q R S T$ upon $A B=M N+N K+K L+L H=M H$;

but $M H$ is the projection of the straight line $P T$ which joins the first initial to last terminal point of the broken line. In the same way it may be shown that the projection of any broken line upon a straight line equals the projection, upon the same straight line, of the straight line which joins the extremities of the broken line. It follows, therefore, that the projection of the perimeter of any closed polygon upon any given line is zero.

If $\theta_{1}, \theta_{2}, \theta_{8}, \theta_{4}$, and $\theta_{5}$ be the angles that $P Q, Q R, R S$, $S T$, and $P T$ respectively make with the line $\Lambda B$, then the projection of the broken line upon $A B$ may also be expressed thus :
proj. $P Q R S T$ upon $A B=M N+N K+K L+L H=M H$

$$
\begin{aligned}
& =P Q \cos \theta_{1}+Q R \cos \theta_{2}+R S \cos \theta_{8}+S T \cos \theta_{4} \\
& =P T \cos \theta_{6} .
\end{aligned}
$$

The projections of two parallel segments of equal length upon any given line in space are equal. It therefore follows that:
(1) The projection of a segment of a line upon any straight
linse in space equals the product of its length by the cosine of the angle between the two lines.
(2) The projection of any broken line in space upon any straight line equals the projection, upon the satme line, of the straight line which joins the extremities of the broken line.

## EXERCISES

1. Twe lines of lengths 3 and 7 renpectively meet at an angle $\frac{\pi}{3}$; find the projection of each upon the other.
2. The center of an equilateral triangle, of side 3 , is joined by a atraight line to a vertex; find the projection of this joining line upon each side of the triangle.
3. A rectangle has its sides resprectively 4 and 6 ; find their projections upon a diagonal.
4. Find the length of the projection of each edge of a cube upon a choeen diagonal.
5. A given line $A B$ makes an angle of $3 \rho$ with the line $M N$, and $B C$ is perpendieular to $A B$ and of length 15 ; find the projection of $B C$ upon $M N$.

Solve this problem if the given angle the a instend of $300^{\circ}$.
6. Two lines in space, of length $a$ and $b$ respectively, make an angle $\omega$ with each other; find the projection of $b$ upon a line that is perpen. dicular to $a$.
7. Project the perimeter of a syuare upon one of its diagonals.

## CHAPTER II

## GEOMETRIC CONCEPTIONS. THE POINT

## 1. COÖRIINATE SYSTEMS

18. Coördinates of a point. Position, like magnitude, is relative, and can be given for a geometric figure only by reference to some fixed geometric figures (planes, lines, or points) which are regarded as known, just as magnitude can be given only by reference to some standard magnitudes which are taken as units of measurement. The position of the city of New York, for example, when given by its latitude and longitude, is referred to the equator and the meridian of Greenwich, - the position of these two lines being known, that of New York is also known. So also the position of Baltimore may be given by its distance and direction from Washington; while a particular point in a room may be located by its distances from the floor and two adjacent walls.

If, as in the last illustration, a point is to be fixed in space, then three magnitudes must be known, referring to three fixed positions. If, on the other hand, the point is on a known surface, as New York or Baltimore on the surface of the earth, then only two magnitudes need be known, referring to two fixed positions on that surface; while if the point is on a known line, only one magnitude, referring to one fixed position on that line, is needed to fix its position.

Those varions magnitudes which serve to fix the position
of a point, - is space, on a surface, or on a line, - are called the coordinates of the point.
19. Analytic Geometry. Courdinates may lee repremented by algebraie numbers; the relations of the various fmints, and the properties of the various geometric figures which are formed by those points, can be studied through the corresponding relations of these algebraic numbers, or courdinates. expressed in the form of algebraic equations. This fact is the basis of analytic, or algebraic, geometry, the main object of which is the study of geometric properties by algebraic methods.

Analytie geometry may be conveniently divided into two prits: Plane Analytic Geometry, which treats only of figures in a gisen plane surface ; and Solid Analytic Geometry, which treats of space figures, and includes Plane Analytic Geometry as a special case. The plane analytio geometry, being the simpler, will be studied first, in Part 1 of this book, and Part II will be devoted to the study of the solid analytie geometry. In this first part of the subject it will therefore be understood that the work is restricted to a given plane surface.

Twn systems of coorrdinates will be used, the Cartesian and the Polar. They are explained in the next few articles.
20. Positive and negative coordinates. If a proint lies in a given directed straight line, its position with reference to a fixed point of that line is completely determined by one coördinate. E.y., let $X^{\prime} O X$ be a

Fio. 6. given directed straight line, and let distances from $O$ toward $X$ be regarded as positive. then distances from $O$ toward $X^{\prime}$ are negative. A point $P$
in this line and 3 units from $O$ toward $X$ may be designated by -3 , where the sign + gives the direction of the point, and the number 3 its distance, from $O$. Inder these circumstances the point $P^{\prime}$ lying 3 units on the other side of $O$ would be designated by -3 .

In the same way there corresponds to every real number, positive or negative, a definite point of this directed straight line; the numbers are called the coordinates of the points; and $O$, from which the distances are measured, is called the origin of coördinates.
21. Cartesian coordinates of points in a plane. Suppose two directed straight lines $X^{\prime} O X$ and $Y^{\prime} O Y$ are given, fixed in the plane and intersecting in the point $O$. These two given lines are called the coordinate axes, $X^{\prime} O X$ being the $x$-axis, and $Y^{\prime} O Y$ being the $y$-axis ; their point of intersection $O$ is the origin of coördinates. Any other two lines,
 parallel respectively to these fixed lines, and at known distances from them, will intersect in one and but one point $P$, whose position is thus definitely fixed. If these lines through $P$ meet the axes in $M$ and $L$ respectively, then the directed distances $L P$ and $M P$, measured parallel respectively to the axes, are the Cartesian coirdinates of the point $P$. The distance $L P$, or its equal $O M$, is the abscissa of $P$, and is usually represented by $x$, while $M P$, or its equal $O L$, is the ordinate of $P$, and is usually represented by $y$. The point $P$ is designated by the symbol $(x, y)$, -often written $P \equiv(x, y)$. - the abscissa always being written first, then a comma, then the ordinate, and both letters being
inclosed in a parenthesis. Thus the point $(4,5)$ is the point for which $O M=4$ and $M P=5$; while the poist $(-3,2)$ has $U . M=-3$ and $M P=2$.
22. Rectangular coordinates. The simplest and must common form of Cartesian coordinate axes is that in which the angle $X O Y$ is a positive right angle; the abscissa ( $x$ ) of a point is, in this case, its perpendicular distance from the $y$-axis, and its ordinate $(y)$ is its perpendicular distance from the $x$-axis. This way of locating the points of a plane is known as the rectangular system of coordinates.

Fio. : b

The axes divide the entire plane into four parts cnlled quadrants, which are usually designated as first (I), second (II). third (III), and fourth (IV), in the order of rotation from the positive end of the $x$-axis toward the positive end of the $y$-axis, as indicated in the accompanying figure.

These quadrants are distinguished by the signs of the coordinates of the points lying within them, thus:
in quadrant I the abscissa $(x)$ is + , the ordinate $(y)$ is + ; in quadrant II the abscissa $(x)$ is - , the ordinate $(y)$ is + ; in quadrant III the abscissa $(x)$ is - , the ordinate $(g)$ is - ; in quadrant IV the abscissa $(x)$ is + , the ordinate $(y)$ is - .

Four points having numerically the same coürdinates, hut lying one in each quadrant, are symmetrical in pairs with regard to the origin, even though the axes are not at right angles; if, however, the axes are rectangular, then these points are symmetrical in pairs, not merely with regard to the origin as before, but also with regard to the axes, and
they are severally equidistant from the origin. Because of this greater symmetry rectangular coorrdinates have many advantages over an oblique system.

In the following pages rectangular coördinates will alurays be understood unless the contrary is expressly stated.

## EXERCISES

1. Plot accurately the points: $\cap, 7),(-4,-5),{ }^{\bullet}(0,3)$, and $(-3,0)$.
2. Plot accurately, as vertices of a triangle, the points: $(1,3),(2,7)$, and $(-4,-4)$. Find by measurement the lengths of the sides, and the coordmates of the middle point of each side.
3. Construct the two lines passing through the points $(2,-7)$ and $(-2,7)$, and $(2,7)$ and $(-2,-7)$, respectively. What is their point of intersection? Find the coordinates of the middle point of each line.
4. If the ordinate of a point is 0 , where is the point? if its ahscissa is 0 ? if its abscissa is equal to its ordinate? if its abscissa and ordinate are numerically equal but of opposite signs?
5. Express each of the conditions of Ex. 4 by means of an equation.
6. The base of an equilateral triangle, whose side is 5 inches, coincides with the $x$-axis; its middle point is at the origin ; what are the courdinates of the vertices? If the axes are chosen so as to coincide with two sides of this triangle, respectively, what are the coordinates of the vertices?
7. A square whose side is 5 inches has its diagonals lying upon the coordinate axes; find the coördinates of its vertices. If a diagonal and an adjacent side are chosen as axes, what are the coördinates of the vertices? of the middle points of the sides? of the center?
8. Find, by similar triangles, the coordinates of the point which bisects the line joining the points $(2,7)$ and $(4,4)$.
9. Show that the distance from the origin to the point $(a, l)$ is $\sqrt{a^{2}+b^{2}}$. How far from the origin is the point $(a,-b)$ ? $(-a, b)$ ? ( $-a,-b$ )? (cf. Art. 22.)
10. Prove by similar triangles, that the points: $(2,3),(1,-3)$, and $(3,9)$ lie on the same straight line.
11. Solve exercises 1 to 4 and 10 if the coiordinate axes make an angle of $60^{\circ}$. Also if this angle be $45^{\circ}$.

[^3]23. Polar coordinates. If a fixed point $O$ is given in a fixed directed straight line $O R$, then the position of any point $P$ of the plane will be fully determined by its distance

$O P=\rho$ from the fixed point, and by the angle $\theta$ which the lime $O P$ makes with the fixed line.

The fixed line $O R$ is called the initial line or polar axis, the fixed point $O$ the pole of the system, and the polar coordinates of the point $P$ are the radius vector $\rho$ and the directional or vectorial angle $\theta$. The usual rule of signs applies to the vectorial angle $\boldsymbol{\theta}$, and the radius vector is positive if measured from $O$ along the terminal side of the angle $\theta$. The point $P$ is designated by the symbol $(\rho, \theta)$.

From what has just been said it is clear that one pair of polar coobrdinates (i.c., one value of $p$ and one of $\theta$ ) serve to determine one, and but one, point of the plane. On the other hand, if $\boldsymbol{\theta}$ is restricted to values lying between 0 and $2 \pi$, then any given point may be designated by four different
pairs of coōrdinates.

Fio. 9.f

E.g., the polar coirrdinates $\left(3,60^{\circ}\right)$ determine the position of the point $P$, for which $O P=3$, and makes an angle of $60^{\circ}$
with the initial line $O R$, but the same point may be given equally well by the pairs of coördinates: $\left(-3,240^{\circ}\right)$, $\left(3,-300^{\circ}\right)$, and $\left(-3,-120^{\circ}\right)$; and so in general.

## EXERCISES

1. Plot accurately the following points: $\left(2,20^{\circ}\right),\left(2, \frac{\pi}{9}\right),\left(-7, \frac{\pi}{2}\right)$, $\left(4 \pi, \frac{\pi^{(r)}}{3}\right),\left(2,14 \pi^{\circ}\right),\left(-1,-180^{\circ}\right),\left(7,-45^{\circ}\right),\left(-7,135^{\circ}\right), \quad\left(5, \frac{3 \pi}{4}\right)$, $\left(0, \frac{\pi}{3}\right),\left(0, \frac{-\pi}{3}\right),\left(6,0^{\circ}\right)$, and $\left(-6,0^{\circ}\right)$.
2. Construct the triangle whose vertices are: $\left(2, \frac{\pi}{8}\right),\left(3, \frac{3 \pi}{4}\right)$, $\left(1, \frac{5 \pi}{4}\right)$; find by measurement the lengths of the sides and the coordinates of their middle points.
3. The base of an equilateral triangle, whose side is 5 inches, is taken as the polar axis, with the vertex as pole; find the coördinates of the other two vertices.
4. Write three other pairs of coördinates for each of the points $\left(2, \frac{\pi}{4}\right) ;\left(-3,75^{\circ}\right) ;\left(5,0^{\circ}\right) ;\left(0,60^{\circ}\right)$.
5. Where is the point whose radius vector is 7 ? whose radius vector is -7 ? whose vectorial angle is $25^{\circ}$ ? whose vectorial angle is $0^{(r)}$ ? whose vectorial angle is $-180^{\circ}$ ?
6. Express each of the conditions of Ex. 5 by means of an equation.
7. What is the direction of the line through the points $\left(3, \frac{\pi}{4}\right)$ and $\left(3, \frac{3 \pi}{4}\right)$ ?
8. Notation. In the following pages, to secure uniformity and in accordance with Art. 6, a variable point will be desig-
nated by $P$, and its coordinates by $(x, y)$ or $(\rho, \theta)$. If several variable points are under consideration at the same time, they will be designated by $P, P^{\prime}, P^{\prime \prime}, P^{\prime \prime \prime}, \ldots$, and their coofrdinates by $(x, y),\left(x^{\prime}, y^{\prime}\right),\left(x^{\prime \prime}, y^{\prime \prime}\right),\left(x^{\prime \prime \prime}, y^{\prime \prime \prime}\right), \cdots$, or by $(\rho, \theta),\left(\rho^{\prime}, \theta^{\prime}\right),\left(\rho^{\prime \prime}, \theta^{\prime \prime}\right),\left(\rho^{\prime \prime \prime}, \theta^{\prime \prime \prime}\right), \cdots$. Fixed points will be designated by $P_{1}, P_{2}, \cdots$, and their coôrdinates by $\left(x_{1}, y_{1}\right),\left(x_{y}, y_{2}\right), \cdots$ or by $\left(\rho_{1}, \theta_{1}\right),\left(\rho_{3}, \theta_{2}\right), \cdots$.

## II. ELEMENTABY Applications

25. The methots of representing a point in a plane that have been adopted in the previous articles lead at once to several easy applications, such as finding the distance between two points, the area of a triangle, etc. The form of the results will depend upon the particular system of coördinates chosen, but the method is the same in each case. Here, as in the more difficult problems that arise later, to gain the full advantage of the analytic method the student should freely use geometric constructions to guide his algebraie work, but he should, at the same time, see clearly that the method is essentially algebraic.

## 26. Distance between two points.

(1) Polar coördinates. Let $O R$ be the initial line, $O$ the pole, and let $P_{1} \equiv\left(\rho_{1}, \theta_{1}\right)$ and $P_{3} \equiv\left(\rho_{2}, \theta_{3}\right)$ be the two given

Fio. 10. ${ }^{\circ}$

- The demonstration applies weach figure.
fixed points. It is required to find the distance $P_{1} P_{2}=d$ in terms of the given constants $\rho_{1}, \rho_{2}, \theta_{1}$, and $\theta_{2}$. In the triangle $O P_{1} P_{2}$ (cf. Art. 16)

$$
\begin{gather*}
\overline{P_{1} P_{3}^{2}=} \overline{O P_{1}^{2}+\overline{O P_{3}^{2}}-2 \cdot O P_{1} \cdot O P_{3} \cdot \cos P_{1} O P_{2}}, \\
d^{2}=\rho_{1}^{2}+\rho_{2}^{2}-2 \rho_{1} \rho_{2} \cos \left(\theta_{2}-\theta_{1}\right), \\
\quad \boldsymbol{d}=\sqrt{\rho_{1}^{2}+\rho_{2}^{2}-2 \rho_{1} \rho_{2} \cos \left(\theta_{3}-\theta_{1}\right)} . \quad . \tag{1}
\end{gather*}
$$

i.e.,
hence
(2) Cartesian coördinates; axes not rectangular. Let $O X$ and $O Y$ be the coördinate axes, meeting at an angle

$X \circ Y=\omega, *$ and let $P_{1} \equiv\left(x_{1}, y_{1}\right)$ and $P_{2} \equiv\left(x_{2}, y_{2}\right)$ be the two given points ; it is required to find the distance $P_{1} P_{2}=d$ in terms of $x_{1}, x_{2}, y_{1}, y_{2}$, and $\omega$.

Construction : Extend the abscissa $L_{1} P_{1}$ of the point $P_{1}$ to meet the ordinate $M_{2} P_{2}$ of the point $P_{2}$, in $Q$; then in the triangle $P_{1} Q P_{2}$ (cf. Art 16)
$\bar{P}_{1} P_{2}^{2}=\bar{P}_{1} Q^{2}+{\overline{Q P_{2}}}^{2}-2 \cdot P_{1} Q \cdot Q P_{2} \cdot \cos P_{1} Q P_{2}$, Fig. $11^{a}$, $P_{1} P_{2}^{2}=\bar{P}_{1} Q^{2}+\bar{P}_{2} Q^{2}-2 \cdot P_{1} Q \cdot P_{2} Q \cdot \cos P_{1} Q P_{2}$, Fig. $11^{b}$, $\overline{P_{1} P_{2}^{2}=} \overline{Q P}_{1}^{2}+P_{2} Q^{2}-2 \cdot Q P_{1} \cdot P_{2} Q \cdot \cos P_{1} Q P_{2}$, Fig. $11^{c}$; which gives, for each figure,

$$
d=\sqrt{\left(x_{1}-x_{2}\right)^{2}+\left(y_{1}-y_{2}\right)^{2}+2\left(x_{1}-x_{2}\right)\left(y_{1}-y_{2}\right) \cos \omega . \dagger}
$$

- The demonstration applies to each figure.
- By examining other possible constructions the student should assure himself of the generality of this formula.
(3) Rectangular coerdinates. If $\omega=\frac{\pi}{2}$, i.e. if the corordinate axes are rectangular, then $\cos \omega=0$, and the formula for the distance between the two given proints becomes

$$
\begin{equation*}
d=\sqrt{\left(x_{1}-x_{2}\right)^{2}+\left(y_{1}-y_{2}\right)^{2}} . \tag{9}
\end{equation*}
$$

Since e-ther of the two points may be nameal $P_{1}$, this formula may be expressed in words thus: In rectangular coördinates, the square of the distance between two given points is the suaare of the difference between their abscissas plus the square of the difference between their ordinates.
27. Slope of a line. By the slope of a line is meant the tangent of the angle which the line makes with the prositive end of the $x$-axis.*

From this definition it at once follows that the slope $m$ of the line joining the two points $P_{1} \equiv\left(x_{1}, y_{1}\right)$ and $P_{2} \equiv\left(x_{2}, y_{2}\right)$, the axes being rectangular, is $m=\frac{Q P_{\mathrm{g}}}{P_{1} Q}$; that is,

$$
\begin{equation*}
m=\frac{y_{2}-y_{1}}{x_{3}-x_{1}} \tag{3}
\end{equation*}
$$

## EXERCISES

1. Find the distances hetween the points $(1,3),(2,7)$, and $(4,-4)$, taken in pairs.
2. Find the distances for the points of Ex. 1, if the axes are ollifique with $\omega=60^{\circ}$.
3. Prove that the points $(-2,-1),(1,0),(4,3)$, and $(1,2)$ are the vertices of a parallelogram.
4. Find the distance betreen the points $(a+b, c+a)$ and $(c+a, b+c)$ : also between $(a, b)$ and $(-a,-b)$.
5. Find the distances betweell the points $\left(2,30^{\circ}\right),\left(3, \frac{3 \pi}{4}\right)$, and $\left(1, \frac{8 \pi}{4}\right)$, taken in pairs.

- The aloppe of a roof or of a hill has the same meaning Thus if the slape of a hill (to the horicontal) is ifo, it rives 3 feet vertical in te0 feet haritontal.

```
TAK. A5.GEOM.-3
```

6. Prove that the points $\left(0,0^{*}\right),\left(3, \frac{\pi}{2}\right)$, and $\left(3, \frac{\pi}{16}\right)$ form an equilateral triangle.
7. One end of a line whose length is 13 is at the point $(-4,8)$, the ordinate of the other end is 3 ; what is its abscissa?
8. Express ly an equation the fact that the point $P \equiv(x, y)$ is at the distance 3 from the point $(-2,3)$; from the point $(0,0)$.
9. Express by an equation the fact that the point $P \equiv(x, y)$ is equidistant from the points $(-2,3)$ and $(7,5)$.
10. Find the slopes of the lines which join the following pairs of points: $(3,8)$ and $(-1,4) ;(2,-3)$ and $(7,9) ;(1,-4)$ and $(-3,5) ;(4,-2)$ and ( $-2,-1$ ).
11. One great advantage of the analytic method of solving problems lies in the fact that the analytic results which are obtained from the simplest arrangement of the geometric figure with reference to the coördinate axes are, from the very nature of the method, equally true for all other arrangements. Thus formulas [1], [2], and [3] can be most readily obtained if the points are all taken in quadrant I, i.e., with their coördinates all positive ; but because of the convention adopted concerning the signs as essential parts of the coördinates, these formulas remain true for all possible positions of $P_{1}$ and $P_{2}$. By drawing the figures and making the proofs when $P_{1}$ and $P_{2}$ are taken in various other positions, the student should assure himself of the generality of formulas [1]. [2], and [3] of articles 26 and 27.

## 29. The area of a triangle.

1. Rectangular coördinates. Given a triangle with the vertices $P_{1} \equiv\left(x_{1}, y_{1}\right), P_{2} \equiv\left(x_{2}, y_{2}\right)$, and $P_{3} \equiv\left(x_{3}, y_{3}\right)$; to find its area in terms of $x_{1}, x_{2}, x_{2}, y_{1}, y_{2}$, and $y_{3}$. Draw the ordinates $M_{1} P_{1}, M_{2} P_{2}$, and $M_{3} P_{3}$, -in the second figure extend $M_{1} P_{1}$ and $M_{3} P_{3}$ to meet a line through $P_{2}$ parallel to the $x$-axis. If $\Delta$ represents the area of the triangle in the first figure, then :

Fio. 12. 9

Fu. Le. ${ }^{\text {® }}$

$$
\Delta=P_{1} M_{1} M_{3} P_{3}+P_{3} M_{2} M_{3} P_{3}-P_{1} M_{1} M_{2} P_{8}
$$

but $P_{1} M_{1} M_{3} P_{2}=\frac{1}{2}\left(M_{1} P_{1}+M_{2} P_{2}\right) \cdot M_{1} M_{3}=\frac{1}{2}\left(y_{1}+y_{3}\right)\left(x_{3}-x_{1}\right)$,
and $P_{2} M_{2} M_{2} P_{2}=\frac{1}{2}\left(M_{3} P_{3}+M_{2} P_{2}\right) \cdot M_{3} M_{2}=\frac{1}{2}\left(y_{3}+y_{2}\right)\left(r_{2}-r_{3}\right)$, and $P_{1} M_{1} M_{2} P_{3}=\frac{1}{2}\left(M_{1} P_{1}+M_{2} P_{2}\right) \cdot M_{1} M_{3}=\frac{1}{2}\left(y_{1}+y_{2}\right)\left(x_{2}-x_{2}\right)$.
$\therefore \Delta=\frac{1}{2}\left\{\left(y_{1}+y_{3}\right)\left(x_{3}-x_{1}\right)+\left(y_{3}+y_{2}\right)\left(x_{2}-x_{3}\right)\right.$

$$
\begin{aligned}
& \left.-\left(y_{1}+y_{2}\right)\left(x_{2}-x_{1}\right)\right\} \\
= & \left\{\left(y_{1}+y_{2}\right)\left(x_{1}-x_{2}\right)\right. \\
& +\left(y_{3}+y_{2}\right)\left(x_{3}-x_{8}\right) \\
& \left.+\left(y_{3}+y_{1}\right)\left(x_{3}-x_{1}\right)\right\} \ldots[4]
\end{aligned}
$$

This may also be written in the form

$$
\Delta=\frac{1}{1}\left\{x_{1}\left(y_{2}-y_{8}\right)+x_{2}\left(y_{3}-y_{1}\right)+x_{3}\left(y_{1}-y_{3}\right\}^{\circ} \cdots[4 a]\right.
$$

So also if $\Delta_{1}$ represents the area of the triangle in the second figure, then

$$
\begin{aligned}
\Delta_{1}= & P_{1} H_{1} H_{3} P_{3}-P_{1} H_{1} P_{3} \quad P_{3} H_{3} P_{3} \\
= & \frac{1}{1}\left\{\left(H_{1} P_{1}+H_{3} P_{3}\right) \cdot M_{1} M_{3}-H_{1} P_{1} \cdot H_{1} P_{2}-H_{3} P_{3} \cdot P_{2} H_{3}\right\}, \\
= & \frac{1}{2}\left\{\left(y_{1}-y_{2}+y_{3}-y_{2}\right)\left(x_{3}-x_{1}\right)-\left(y_{1}-y_{2}\right)\left(x_{2}-x_{1}\right)\right. \\
& \left.\quad-\left(y_{3}-y_{2}\right)\left(x_{3}-x_{2}\right)\right\},\left[x_{1}, x_{2} \text { and } y_{3} \text { being negative }\right] \\
= & \frac{1}{2}\left\{x_{1}\left(y_{3}-y_{2}\right)+x_{2}\left(y_{8}-y_{1}\right)+x_{3}\left(y_{1}-y_{2}\right)\right\} \text {,t as above [t a]. }
\end{aligned}
$$

- In the determinant notation this may be Written: ares of the triangle $=1\left|\begin{array}{lll}x_{1} & y_{1} & 1 \\ x_{\mathrm{n}} & y_{\mathrm{t}} & 1 \\ x_{\mathrm{in}} & y_{\mathrm{t}} & 1\end{array}\right|$.

T This is derived by another method in Ex. 12, p. 129

If, instead of rectangular coördinate axes, oblique axes making an angle $X O Y=\omega$ had been used, it would have been necessary merely to multiply the second members in the results just found by $\sin \omega$ in order to express the areas of the triangles.

Fio. 18.
2. Polar coorrdinates. Let the vertices of the triangle be $P_{1} \equiv\left(\rho_{1}, \theta_{1}\right)$, $P_{2} \equiv\left(\rho_{2}, \theta_{2}\right)$, and $P_{3} \equiv$ $\left(\rho_{3}, \theta_{3}\right)$; to find its area $\Delta$ in terms of $\rho_{1}, \rho_{3}, \rho_{3}, \theta_{1}$, $\theta_{2}$, and $\theta_{3}$.
Manifestly, $\quad \Delta=O P_{2} P_{3}+O P_{3} P_{1}-O P_{2} P_{1}$,
but $O P_{2} P_{3}=\frac{1}{2} \rho_{2} \rho_{3} \sin \left(\theta_{3}-\theta_{2}\right), O P_{3} P_{1}=\frac{1}{2} \rho_{3} \rho_{1} \sin \left(\theta_{1}-\theta_{3}\right)$,

$$
\text { and } O P_{2} P_{1}=\frac{1}{2} \rho_{2} \rho_{1} \sin \left(\theta_{1}-\theta_{2}\right) \text {. }
$$

$\therefore \Delta=\frac{1}{2}\left\{\rho_{2} \rho_{3} \sin \left(\theta_{3}-\theta_{2}\right)+\rho_{3} \rho_{1} \sin \left(\theta_{1}-\theta_{3}\right)-\rho_{2} \rho_{1} \sin \left(\theta_{1}-\theta_{2}\right)\right\}$, which may also be written

$$
\begin{align*}
\Delta=\frac{1}{2}\left\{\rho_{1} \rho_{2} \sin \left(\theta_{2}-\rho_{1}\right)\right. & +\rho_{2} \rho_{3} \sin \left(\theta_{3}-\theta_{2}\right) \\
& \left.+\rho_{3} \rho_{1} \sin \left(\theta_{1}-\theta_{3}\right)\right\} . \tag{5}
\end{align*}
$$

The symmetry* in formulas [4], [4a], and [5] should be carefully noted; it may be remarked also, that in the application of these formulas to numerical examples, the resulting areas will be positive or negative according to the relative order in which the vertices are named.

[^4]
## ExERCISEs

1. Find the arvas of the following triangles: (1) vertiess at the promts (3, 5), (1,2), and (1, 3) (2) vertiees at the prints $(7,3),(4,6)$, and $(3,-2)!$ ( 3 ) vertiens at tho prints $(11,0),(3,-2)$, and $(-3,3)$.

Sntie withent using the formula, and thein verify by nututituting in the formula.
2. Prove that the area of the triangle whowe vertioss are at the points $(2,3),(3,4)$ and $(-1,1)$ is zero, and hence that these points all lie on the same straight line.
3. Do the joints $(2,3),(1,-3)$, and $(3,9)$ lie on one atraight line? (cf. Ex. 10, p. 28.)
4. Tho the peoints $\left(7,30^{\circ}\right),\left(0,0^{\circ}\right)$, and $\left(-11,210^{\circ}\right)$ lie on one straight line? Solve this by showing that the area of the triangle is zero, and then verity by plotting the figure.
5. Find the area of the triangle $\left(\pi, \frac{\pi^{\prime \prime \prime}}{2}\right),\left(2 \pi, \frac{\pi^{(n)}}{2}\right)$, and $\left(-\pi, \frac{2 \pi^{n+n}}{3}\right)$.
6. Derive formula [1] when $P_{1}$ is in quadrant $I 1, P_{2}$ in quadrant III, and $P_{3}$ in quadrant IV.
7. Find the area of the first two triangles in Ex. 1 if the axes make an angle of $60^{\circ}$ with each other.

## 30. To find the coordinates of the point which divides in

 a given ratio the straight line from one given point to another. Let $P_{1} \equiv\left(x_{1}, y_{1}\right)$ and $P_{2} \equiv\left(x_{3}, y_{2}\right)$ be the two given points, $P_{3} \equiv\left(r_{3}, y_{3}\right)$ the required point, and let the

ratio of the parts into which $P_{3}$ divides $P_{1} P_{3}$ be $m_{1}: m_{2}$; i.e., let $P_{1} P_{2}: P_{3} P_{2}=m_{2}: m_{3}$. Draw the ordinates $M_{1} P_{1}$.
$M_{2} P_{2}, M_{8} P_{3}$, and through $P_{1}$ and $P_{3}$ draw lines parallel to $O X$, meeting $M_{3} P_{3}$ and $M_{2} P_{3}$ in $R$ and $Q$ respectively.
To find $O M_{3}=x_{3}$ and $M_{3} P_{3}=y_{3}$ in terms of $x_{1}, x_{2}, y_{1}, y_{3}$, $m_{1}$, and $m_{2}$.

The triangles $P_{1} R P_{3}$ and $P_{8} Q P_{2}$ are similar ;
therefore

$$
\frac{P_{1} R}{P_{8} Q}=\frac{R P_{3}}{Q P_{2}}=\frac{P_{1} P_{3}}{P_{3} P_{2}} .
$$

But

$$
\frac{P_{1} P_{8}}{P_{3} P_{2}}=\frac{m_{1}}{m_{2}}
$$

and

$$
\begin{aligned}
& P_{1} R=x_{8}-x_{1}, \quad P_{8} Q=x_{2}-x_{3}, \\
& R P_{3}=y_{3}-y_{1}, Q P_{2}=y_{2}-y_{3} .
\end{aligned}
$$

[In Fig. 14 (b), $x_{1}, y_{1}, y_{2}$, and $y_{3}$ are negative.]
therefore

$$
\frac{x_{3}-x_{1}}{x_{2}-x_{3}}=\frac{y_{3}-y_{1}}{y_{2}-y_{3}}=\frac{m_{1}}{m_{2}} ;
$$

whence

$$
\begin{equation*}
x_{3}=\frac{m_{1} x_{2}+m_{2} x_{1}}{m_{1}+m_{2}} \text { and } y_{3}=\frac{m_{1} y_{2}+m_{2} y_{1}}{m_{1}+m_{2}} . \tag{6}
\end{equation*}
$$

The above reasoning applies equally well whatever the value of $\omega$ (the angle made by the coördinate axes), hence formulas [6] hold whether the axes be rectangular or oblique.

Formulas [6] were obtained on the implied hypothesis that $P_{8}$ lies between $P_{1}$ and $P_{2}$; i.e., that $P_{3}$ is an internal point of division. If $P_{8}$ is taken in the line $P_{1} P_{2}$ produced, and not between $P_{1}$ and $P_{2}$, it still forms, with $P_{1}$ and $P_{2}$, two segments $P_{1} P_{8}$ and $P_{8} P_{2}$, and $P_{8}$ may be so taken that, numerically, the ratio of $P_{1} P_{3}: P_{8} P_{2}$ may have any real value whatever; but the sign of this ratio is negative when $P_{3}$ is not between $P_{1}$ and $P_{2}$, for, in that case, the segments $P_{1} P_{8}$ and $P_{3} P_{2}$ have opposite directions. Hence, to find the coördinates of that point which divides a line externally into segments whose numerical ratio is $m_{1}: m_{2}$, it is only
necessary to prefix the minus sign to either one of the two numbers $m_{1}$ or $m_{2}$ in formulas [6]. These formulas then become

$$
\begin{equation*}
x_{3}=\frac{m_{1} x_{3}-m_{3} x_{1}}{m_{1}-m_{2}}, y_{8}=\frac{m_{1} y_{3}-m_{2} y_{1}}{m_{1}-m_{2}} . \tag{i}
\end{equation*}
$$

Cor. If $P_{8}$ be the middle point of $P_{1} P_{2}$, then $m_{1}=m_{c}$ and formulas [6] become

$$
\begin{equation*}
x_{3}=\frac{x_{1}+x_{2}}{2}, \quad y_{3}=\frac{y_{1}+y_{2}}{2} ; \tag{8}
\end{equation*}
$$

i.e., the abscissa of the middle point of the line joining two given points is half the sum of the abscissas of those points, and the ordinate is half the sum of their ordinates.

The remarks in Art. 28 are well illustrated by formulas [4] to [8].

## EXERCISES

1. By means of an appropriate figure, derive formulas [7] independently of [6].
2. The point $P_{3} \equiv(2,3)$ is one third of the distance from the point $P_{1} \equiv(-1,4)$ to the point $P_{3} \equiv\left(x_{5}, y_{3}\right)$; $w$ find the courdinates of $P_{r}$

Here $P_{1}$ and $P_{3}$ are given, with $x_{1}=-1, y_{1}=1, x_{3}=2, y_{3}=3$, also $m_{1}=1$, and $m_{2}=2$; cherefore, from [ 6 ],

$$
2=\frac{x_{3}+2(-1)}{1+2}, \text { and } 3=\frac{y_{2}+2(4)}{1+2}
$$

which give $x_{3}=8$ and $y_{8}=1$; therefore the required point $P_{3}$ is $(8,1)$
3. Find the points of trisection of the line joining $(1,-2)$ to $(3,4)$.
4. Find the point which divides the line from $(1,3)$ to $(-2,4)$ externally into segments whose numerical ratio is $3: 4$.

Here $x_{1}=1, y_{1}=3, x_{3}=-2, y_{3}=4, m_{1}=3$, and $m_{2}=4$, but the point of division being an external one, the two segments are opposituly directed; therefore one of the numbers 3 or 4 , say 4 , must hiare the minus sign prefixed to it. Substituting these values in [ 6 ],

$$
x_{3}=\frac{3(-2)-4(1)}{3-4}=10, \text { and } y_{3}=\frac{3(4)-4(3)}{3-4}=0 \text {; }
$$

the required point is, therefore, $P_{s} \equiv(10,0)$.

The same result would have been obtained had $m_{1}=3$, instead of $m_{2}=4$, been given the minus sign; or, again, formulas [7] could have been employed to solve this problem.
5. Solve Ex. 4 directly from a figure, without using either [ 8 ] or [ 7 ].
6. Find the points which divide the line from $(1,5)$ to $(2,7)$ internally and externally into segments which are in the ratio $2: 3$.
7. A line $A B$ is produced to $C$, so that $B C=1 A B$; if the points $A$ and $B$ have the coordinates $(5,6)$ and $(7,2)$, respectively, what are the coördinates of $C$ ?
8. Prove, by means of Art. 30, that the median lines of a triangle meet in a point, which is for each median the point of trisection nearest the side of the triangle.
31. Fundamental problems of analytic geometry. The elementary applications already considered have indicated how algebra may be applied to the solution of geometric problems. Points in a plane have been identified with pairs of numbers, - the coördinates of those points, - and it has been seen that definite relations between such points correspond to definite relations between their coördinates.

It will be found also that the relation between points. which consists in their lying on a definite curve, corresponds to the relation between their coördinates, which consists in their satisfying a definite equation. From this fact arise the two fundamental problems of analytic geom. etry :

1. Given an equation, to find the corresponding geometric curve, or locus.
2. Given a geometric curve, to find the corresponding equation.

When this relation between a curve and its equation has been studied, then a third problem arises :

1II. To find the properties of the curve from those of its equation.

The first two prohlems will be treated in the two sucesed. ing chapters, while the remaining chapters of Part I will be concerned chiefly with the third problem. In this application of analytic methods, bowever, only algeloraie equations of the first and second degrees will for the most part be considered. In Chapter XIII is given a brief study of other important equations and curves.

## EXAMPLES ON CHAPTER II

1. Find the area of the quadrilateral whose vertices are the pointe $(1,0),(3,1),(-1,16)$, and $(-1,2)$. Draw the figure.
2. Find the lengthes of the sides and the altitude of the isosceles triangle $(1,5),(5,1),(-3,-9)$. Find the area by two different methodes, so that the results will each be a check on the other.
3. Find the ooordinates of the point that divides the line from (2, 3) to (-1, -6) in the ratio $3: 4$; in the ratio $2:-3$; in the ratio $3:-2$. Draw each Egure.
4. One extremity of a atraight line is at the point $(-3,4)$, and the line is divided by the point $(1,6)$ in the ratio $2: 3$; find the other extremity of the line.
5. The line from $(-8,-2)$ to $(3,-1)$ is divided in the ratio $4: 5$; find the distance of the point of division from the proint $(-7,6)$.
6. Find the area and also the perimeter of the triangle whose vertiees are the points $(3,60),\left(5,120^{\circ}\right)$, and $\left(8,30^{\circ}\right)$.
7. Show analytically that the figure formed lyy joining the middle [mints of the sides of any quadrilateral is a parallelogram.
8. Sbov that the points $(1,3),(2, \sqrt{6})$, and $(2,-\sqrt{6})$ are equidistant from the origin.
9. Show that the points $(1,1),(-1,-1)$ and $(+\sqrt{3},-\sqrt{3})$ form an equilateral triangle. Find the slopes of its sides.
10. Prove analytically that the diagomals of a metangle are equal.
11. Show that the points $(0,-1),(2,1),(0,3)$, and $(-2,1)$ are the vertices of a square.
12. Express by an equation that the point ( $h, k$ ) is equidistant from $(-1,1)$ and $(1,2)$; from $(1,2)$ and $(1,-2)$. Then show that the point $(3,0)$ is equidistant from $(-1,1),(1,2)$, and $(1,-2)$.
13. Prove analytically that the middle point of the hypotenuse of a right triangle is equidistant from the three vertices.
14. Three vertices of a parallelogram are ( 1,2 ), $(-5,-3)$, and $(7,-6)$; what is the fourth vertex?
15. The center of gravity of a triangle is at the point in which the medians intersect. Find the center of gravity of the triangle whose vertices are ( 2,3 ), $(4,-5)$, and ( $3,-6$ ). (cf. Ex. 8, p. 40.)
16. The line from $\left(x_{1}, y_{1}\right)$ to $\left(x_{2}, y_{2}\right)$ is divided into five equal parts; find the points of division.
17. Prove analytically that the two straight lines which join the middle points of the opposite sides of a quadrilateral mutually bisect each other.
18. Prove that $(1,5)$ is on the line joining the points $(0,2)$ and $(2,8)$, and is equidistant from them.
19. If the angle between the axes is $30^{\circ}$, find the perimeter of the triangle whose vertices are (2, 2), (-7, -1), and ( $-1,5$ ). Plot the figure.
20. Show analytically that the line joining the middle points of two sides of a triangle is half the length of the third side.
21. A point is 7 units distant from the origin and is equidistant from the points $(2,1)$ and $(-2,-1)$; find its coördinates.
22. Prove that the points $(a, b+c),(b, c+a)$, and $(c, a+b)$ lie on the same straight line. (cf. Ex. 2, p. 37.)

## CHAPTER III

## the locus of an equation

32. The locus of an equation. A pair of numbers $x, y$ is represented geometrically by a point in a plane. If these two numbers $(x, y)$ are variables, but connected by an equantion, then this equation can, in general, be satisfied by an infinite number of pairs of values of $x$ and $y$, and each pair may be represented by a point. These points will not, however, be scattered indiscriminately over the plane, but will all lie in a definite curve, whose form depends only upon the nature of the equation under consideration; and this curve will contain no points except those whose anordinates are pairs of values which when substituted for $x$ and $y$, satisfy the given equation. This curve is called the locus or graph of the equation; and the first fundamental problem of analytic geometry is to find, for a given equation, its graph or locus.
33. Illustrative examples: Cartesian coobrdinates.
(1) Given the equation $z+5=0$, to find its locus. This equation is satisfied ly the pairs of values $x_{1}=-5, y_{1}=2 ; x_{2}=-5, y_{2}=3$; $x_{1}=-5, y_{3}=-2$; etc., that is, ly every pair of values for which $x=-5$. Such points as

$$
\begin{aligned}
& P_{1} \equiv\left(x_{1}, y_{1}\right) \equiv(-5,2), \\
& P_{8} \equiv\left(x_{2} y_{2}\right) \equiv(-\delta, 8), \\
& P_{3} \equiv\left(x_{b} y_{2}\right) \equiv(-\delta,-3), \text { cta. }
\end{aligned}
$$

all lie on the line $M N$, parallel to the g-axis, and at the distance 5 on the negative side of it, - this line extending indefinitely in both diree.
tions. Moreover, each point of $M N$ has for its abscissa - 5 , hence the coordinates of each of its points satisfy the equation $x+5=0$. In the chosen system of coördi-
 nates, the line $M N$ is called the locus of this equation.

Similarly, the equation $x-5$ $={ }^{0}$ ) is satisfied by any pair of values of which $x$ is 5 , such as $(5,2),(5,3),(5,4)$, ete.; all the corresponding points lie on a straight line $M^{\prime} N^{\prime}$, parallel to the $y$-axis, at the distance 5 from it, and on its positive side ; i.e., $\boldsymbol{M}^{\prime} \boldsymbol{N}^{\prime}$ is the locus of the equar tion $x-5=0$.
(2) Given the equations $y \pm 3=0$, to find their loci By the same reasoning as in (1) it may be shown that the locus of the equation $y+3=0$ is the straight line $A B$, parallel to the $x$-axis, situated at the distance 3 from it, and on its negative side. Also that the locus of the equation $y-3=0$ is $C D$, a line parallel to the $x$-axis, at the distance 3 from it, and on its positive side.

More generally, it is evident that in Cartesian coürdinates (rectangular or oblique), an equation of the first degree, and containing but one variable, represents a straight line parallel to one of the coördinate axes.'
(3) Given the equation $3 x-2 y+12=0$, to find its locus. In this equation both the variables appear. By assigning any definite value to either one of the variables, and solving the equation for the other, a pair of values that will satisfy the equation is obtained. Thus the following pairs of values are found:

$$
\begin{array}{ll}
x_{1}=0, y_{1}=6 & x_{5}=-1, y_{5}=4 \frac{1}{2} \\
x_{2}=1, y_{2}=71 & x_{6}=-2, y_{6}=3 \\
x_{3}=2, y_{3}=9 & x_{7}=-3, y_{7}=1 \frac{1}{2} \\
x_{4}=3, y_{4}=101 & x_{8}=-4, y_{8}=0 \\
x=+\infty, y=+\infty & x=-\infty, y=-\infty
\end{array}
$$

Plotting the corresponding points
$P_{1}, P_{2}, P_{a}, P_{4} \ldots$, where $P_{1} \equiv\left(x_{1}, y_{1}\right) \equiv(0,6)$, $P_{2} \equiv\left(x_{2}, y_{2}\right) \equiv\left(1,7 \frac{1}{1}\right)$, etc.,

Fra. 10.
they are all found to lie on the straight line $E F$, which is the locus of the equation $3 x-2 y+12=0$.

In Chap. V, it will be shown that, in Carterian courdimates, an equatiof of the first degree in two variables alwags representes a straight lime.
(d) Ciinen the equition $y^{2}=4 \bar{z}, 10$ find its torm. Thits बquation is matisfied by each of the following pain of values, found $m$ in (3) above:
$x_{1}=0, y_{1}=0$
$x_{2}=1, y_{3}=+2$
$x_{3}=1, y_{3}=-2$
$x_{4}=2, y_{4}=2 \sqrt{2}=2.8$, approximately
$z_{3}=2, y_{3}=-2 \sqrt{2}=-2.8$, approximatoly
$x_{6}=2=4, y_{6}=+1$
$y=+\infty, y= \pm \infty$
and for any negative salue of $x$ the correspowding value of $y$ is imaginary.

The corresponding points are:

$$
P_{1} \equiv(0,0), P_{3} \equiv(1,2), P_{3} \equiv(1,-2), \text { etc. }
$$

All these points are found to lie on the curve as plotted in Fig. 17. This curve is called a parabola, and will be studied in a later chapter.

The parabola is one of the curves obtained log the intersection of a circular cone and a plane. (el. Appendix, Note D.) It will be shown in Chap. XII that in Cartesian coordinates, the locus of any alge-

Fia. 18. traic equation in two variables and of the second degree is a "conic section."
(5) Given the equation, $y=25 \log x$, to find its locus. A talle of logarithmes shows that this equation is satisfied by the following pairs of values:

$$
\begin{array}{ll}
x_{1}=0, y_{1}=-\infty & x_{8}=6, y_{7}=19.4 \\
x_{3}=1, y_{2}=0 & x_{8}=7, y_{3}=21.1 \\
x_{3}=2, y_{3}=7.5 & x_{3}=10, y_{3}=25 \\
x_{6}=3, y_{4}=11.9 & x_{10}=15, y_{10}=20.4 \\
x_{5}=4, y_{3}=15 & x_{11}=20, y_{14}=82.5 \\
x_{6}=\delta_{1} y_{6}=17.5 & \text { elc. etc. }
\end{array}
$$

The corresponding points are:
$P_{1} \equiv(0,-\infty), P_{3} \equiv(1,0), P_{2} \equiv(2,7,5)$. ete; and the locus of the alove equation is approsimately given by the curve drawn through these points as shown in Fig. 18.
(6) Given the equation $y=\tan x$, to find its locus. By means of a table of "natural" tangents it is seen that this equation is satisfied by the following pairs of values of $x$ and $y$ :

| Deomes | Radiaxs |  |
| :---: | :---: | :---: |
| $x_{1}=0$ | $=0.00$ | $y_{1}=0$ 。 |
| $x_{3}=10$ | $=0.17$ | $y_{2}=0.18$ |
| $x_{3}=20$ | $=0.35$ | $y_{3}=0.36$ |
| $x_{4}=30$ | $=0.52$ | $y_{4}=0.58$ |
| $x_{5}=40$ | $=0.70$ | $y_{8}=0.84$ |
| $x_{6}=50$ | $=0.87$ | $y_{6}=1.19$ |
| $x_{7}=60$ | $=1.05$ | $y_{7}=1.73$ |
| $x_{8}=70$ | $=1.22$ | $y_{8}=2.75$ |
| $x_{3}=80$ | $=1.40$ | $y_{0}=5.67$ |
| $x_{10}=90$ | $=1.57$ | $y_{10}=\infty$ |
| $x_{11}=-10$ | $=-0.17$ | $y_{11}=-0.18$ |
| $x_{12}=-20$ | $=-0.35$ | $y_{12}=-0.36$ |
| $x_{13}=-30$ | $=-0.52$ | $y_{13}=-0.58$ |

The corresponding points are:

$$
P_{1} \equiv(0,0), P_{2} \equiv(0.17,0.18), P_{3} \equiv(0.35,0.36), \text { etc. }
$$

and the locus is approximately as shown in Fig. 19.

34. Loci by polar coördinates. Analogous results are obtained for a system of polar coördinates, as will be best seen from an example. Given the equation $\rho=4 \cos \theta$, to find its locus.

This equation is satisfiod by the following pains of values, found as in Art. 33 (3) and (1):

| $\theta_{1}=0$ | $p_{1}=1$ |
| :---: | :---: |
| $\theta_{2}=30^{\circ}$ | $p_{3}=2 \sqrt{3}=3.46+$ |
| $\theta_{a}=60^{\circ}$ | $P_{5}=$ ? |
| $\theta_{4}=45^{\circ}$ | $P_{6}=2 \sqrt{2}=2.8+$ |
| $\theta_{3}=160^{\circ}$ | $P_{8}=0$ |
| $\theta_{6}=-30^{\circ}$ | $P_{8}=3.46+$ |
| $6,=-80^{\circ}$ | $P_{g}=2$ |
| $\theta_{0}=-45^{\circ}$ | $P_{0}=2.8+$ |
| $\theta_{0}=-20^{\circ}$ | $P_{0}=0$ |
| ete. | etc. |

The corresponding points are:
$r_{1} \equiv\left(4.0^{\circ}\right) ; \quad P_{3} \equiv\left(3.46+, 30^{\circ}\right) ; \quad P_{3} \equiv\left(2,60^{\circ}\right) ; \quad P_{1} \equiv\left(2.8+, 45^{\circ}\right) ;$ $P_{8}=P_{\mathrm{D}}$ an the pole $\bar{O}=\left(0 . \pm 90^{\circ}\right) ; P_{\mathrm{G}} \equiv\left(3.46+,-30^{\circ}\right) ; P_{8} \equiv\left(2,-60^{\circ}\right)$; ete.

All these points are found to lie on the circumference of a circle whose radius is 2 , the pole being on the circumference, and the polar axis teing a diameter. This cirele is the locus of the equation $\rho=4 \cos \theta$.

## EXERCISES

Plot the loci of the following equations :

1. $x=0$.
2. $y=0$.
3. $b x=0$
4. $8 x=7$.
5. $2 y+5=0$.
6. $x+y=0$.
7. $x^{2}+y^{2}=4$.
8. $x+y=4$.
9. $x-y=0$.
10. $x^{2}-y^{2}=4$.
11. $2 x^{3}+y^{3}=4$
12. $v=32$.
13. $\mu+s^{2}=9$.
14. $u^{8}+v=0$.
15. $s=10 \mathrm{c}$ 。
16. ${ }_{2}^{x}+\frac{y}{3}=1$.
17. $p=3$.
18. $\rho \cos \left(\theta-f 0^{\circ}\right)=5$.
19. $y=-x^{3}$.
20. The locus of an equation. By the process illustrated above, of constructing a curve from its equation, the first conception of a locus is obtained, viz.:
(1) The locus of an equation containing theo mariables is the line or set of lines, which contains all the points whose codrdinates sutiafy the given equation, and which contains no other points. It is the place where all the points, and
only those points, are found whose coordinates satisfy the given equation.

A second conception of the locus of an equation comes directly from this one, for the line or set of lines may be regarded as the path traced by a point which moves along it. The path of the moving point is determined by the condition that its coördinates for every position through which it passes must satisfy the given equation. Thus the line EF (the locus of eq. (3), Art. 33) may be regarded as the path traced by the point $P$, which moves so that its coördinates $(x, y)$ always satisfy the equation

$$
3 x-2 y+12=0
$$

Thus arises a second conception of a locus, viz.:
(2) The locus of an equation is the path traced by a point which moves so that its coorrdinates always satisfy the given equation.

In either conception of a locus, the essential condition that a point shall lie on the locus of a given equation is, that the coördinates of the point when substituted respectively for the variables of the equation, shall satixfy the equation; and in order that a curve may be the locus of an equation, it is necessary that there be no other points than those of this curve whose coörclinates satisfy the equation.
36. Classification of loci. The form of a locus depends upon the nature of its equation; the curve may therefore be classified according to its equation, an algebraic curve being one whose equation is algebraic, and a transcendental curve one whose equation is transcendental. In particular, the degree of an algebraic curve is defined to be the same as the degree of its equation. The following pages are
concerned chiefly with algebraic curves of the firse and second degrees.

## 37. Construction of loci. Discussion of equations. The

 provess of constructing a locus by plotting separate points, and then connecting them by a smooth curve, is only appproximate, and is long and tedious. It may often be shortened by a consideration of the peculiarities of the given eguation, such as symmetry, the limiting values of the variables for which both are real, ete. Such considerations will often show the general form and limitations of the curve; and, taken together, they constitute a discussion of the equation.The points where a locus crosses the coordinate axes are almost always useful ; in drawing the curve, they are given by their distances from the origin along the resprective axes. These distances are called the intercepts of the curve.

The following examples may serve to illustrate these conceptions.
(1) Discussion of the equation $3 z-2 y+12=0$ [see (3) Art. 83].

Interceptas: if $x=0$, then $y=0$; hence the $y$-interrept is 6
(wee Fig. 16); if $y=0$, then $x=-4$; hence the $x$-intereept is 4 .
The equation may be written: $x=3 y-4$, which shows that as $y$ increases continnously from 0 to $\infty, x$ increases continuously from -1 to a : therefore the locus passes from the point $P_{5}$, through the point $P_{v}$, and then recedes indefinitely from both axes in the first quadrant. Written as above, the equation also shows that as $y$ decreases from 0 to $-\infty$. $z$ also decreases from -4 to $-\infty$; therefore the locus passes from $P_{5}$ into the third guadrant, receding again indefinitely from both axes. Sinee for every value of $y, x$ takes but one value (i.e., each value of $y$ corresponds to but one point on the curve), therefore the locus consists of a single branch. The proof that the locus of any first-degree equation, in two rariables, is a straight line is given in Chap. $\boldsymbol{V}$.
(2) Discussion of the equation $y^{3}=42$. [Sve (4) Art. 33.]

Intercepts (see Fig. 17) : if $x=0$, then $y=0$, and if $y=0$, then $x=0$;
hence the locus cuts each axis in one point only, and that point is the origin. The equation may be written in the form $y= \pm \sqrt{4 x}$, which shows that if $x$ be negative $y$ is imaginary; hence there is no point of this locus on the negative side of the $y$-axis.

Again: for each positive value of $x$ there are two real values of $y$, numerically equal, but opposite in sign ; hence this locus passes through the origin, lies wholly in the first and fourth quadrauts, and is symmetrical with regard to the $x$-axis.

The equation shows also that $x$ may have any positive value, however great, and that $y$ increases when $x$ increases; these facts show that the locus recedes indefinitely from both axes, - that it is an open curve of one branch. It is called a parabola and has the form shown in Fig. 17.
(3) Discussion of the equation $x^{2}+y^{2}=a^{2}$.

Intercepts: if $x=0$, then $y= \pm a$, and

Fio. 21. if $y=0$, then $x= \pm a$; hence for each axis there are two intercepts, each of length $a$, and on opposite sides of the origin; i.e., four positions of the tracing point are: $A \equiv(a, 0), A^{\prime} \equiv(-a, 0), B \equiv(0, a)$, and $B^{\prime} \equiv(0,-a)$.

This equation may also be written

$$
y= \pm \sqrt{a^{2}-x^{2}}
$$

which shows that every value of $x$ gives two corresponding values of $y$ which are numerically equal, but of opposite sign ; the locus is, therefore, symmetrical with regard to the $x$-axis. It also shows that, corresponding to any value of $x$ numerically greater than $a$, $y$ is imaginary; the tracing point, therefore, does not move further from the $y$-axis than $\pm a$, i.e., further than the points $A$ and $A^{\prime}$. Moreover, as $x$ increases from 0 to $a, y$ remains real and changes gradually from $+a$ to 0 , or from $-a$ to 0 ; i.e., the tracing point moves continuously from $B$ to $A$, or from $B^{\prime}$ to $A$.

Again, if $x$ decreases from 0 to $-a, y$ remains real and changes continuously from $+a$ to 0 , or from $-a$ to 0 ; i.e., the tracing point moves continuously from $B$ to $A^{\prime}$ or from $B^{\prime}$ to $A^{\prime}$.

Similarly, the equation may be written $x= \pm \sqrt{a^{2}-y^{2}}$, which shows that the curve is also symmetrical with regard to the $y$-axis, and that the tracing point does not move farther than $\pm a$ from the $x$-axis.

From these facts it follows that this locus is a closed curve of only one branch. It is a circle of radius $a$, with its center at the origin; this curve will be studied in detail in Chap. VII.
(4) Discussion of che equation $y^{2}=(s-2)(x-3)(x-4)$.

Intereppts: if $s=0$, then $y$ is imaginary: if $y=0$, then $z=2$, a, op i) hence the locus crusee the s-axes at the throe peinta; $A \equiv[2,0)$, $B \equiv(3,0)$, and $C \equiv(1,0)$, and it doen wot eut the yaxis at all. Moreover, since $y$ is imaghary if $z$ is begative, the locus lies wholly on the positive side of the gaxie.

This locus is symmetrical with regard to the xaxis; it has no point neares to the y-axis than A; letween A and B it cousista of a olosed branch; and it has no real points between $B$ and $C$, but is again real beyond $C$. The entire locus consists, then, of a closed oval, and of an open branch whicis recodes indefinitely from both axes (see Fig. 22).

(5) Discuasion of the equation $y=$ tanz. This equation has already been examined in (8) Art. 33, but in practice it may be much more simply photed by the following method:

Describe a circle with unit ralius; draw the diameter $A O C$, and the lines $O B_{1}, O B_{8}, O B_{3}, \cdots$, meeting the tangent $A T$ in the puints $T_{v}, T_{s}, T_{s}, \cdots$; then the tangent of the angle $A O B_{1}$ is $M_{1} B_{1}: O M_{1}=A T_{1}: O A$ (Ar. 14), and, since $O A=1$, its value is graphically represented by $A T_{1}$. So also

$$
\tan A O B_{2}=M_{3} B_{3}: O M_{3}=A T_{3}: O A=A T_{3}: 1,
$$

and may be graphically represented by $\boldsymbol{A} \boldsymbol{T}_{g}$. In the same way, $A T_{p} A T_{p} A T_{\rho} \cdots$ are the tangents of the angles $A O B_{s} A O B_{e} A O B_{0} \ldots$... Again, since angles at the center of a circle are proportional to the ares intercepted by their sides, $\Delta T_{v}$ $A T_{\text {s }} \cdots$ may be said to be the tangents of the ares $A B_{1}, A B_{n} \cdots$; i.e., $A T_{1}=\tan A B_{1}, A T_{2}=\tan$ $A B_{p} \cdots$. Therefore the coordinintes of the proints $P_{1}=\left(A B_{p}, A T_{2}\right), P_{2} \equiv\left(A B_{p} A T_{2}\right), \cdots$ satisfly the given equation, and if a sufficient number of points. whose coserdinates ane thus determineel, the plotted, they will all lie on a curve like that in Fig. 10.

Prom what has just been said it is clear that $y=0$ if $x=0$, hence the eurve goes through the origin; when $x$ increases continuously from 0 to $\frac{\pi}{2} y$ increases continuously from 0 to $x$, but when $x$ increases through $\frac{\pi}{2}$, $y$ passes suldenly from $+\infty$ to $-\infty$, and the curve is discontinuous for that value of $x$. So also when $x$ increases continuously from $\frac{\pi}{2}$ to $\frac{3 \pi}{2}$, $y$ increases continuously from $-\infty$ through 0 to $+\infty$, and is again discontinuous for $x=\frac{3 \pi}{2}$. The lecus consists of an infinite number of such infinite, but continuous branches, separated by the points of discontinuity for which $x= \pm \frac{\pi}{2}, x= \pm \frac{3 \pi}{2}, x= \pm \frac{5 \pi}{2}, \cdots$.

The other trigonometric functions, $y=\sin x, y=\sec x$, etc., can all be plotted by a method analogous to that above.

## EXERCISES

Construct and discuss the loci of the following equations:

1. $\frac{x^{2}}{4}-\frac{y^{2}}{9}=1$.
2. $y=\sec x$.
3. $v=\sin u$.
4. $x^{2}-y^{2}=a^{2}$.
5. $x^{2}+y^{2}=0$.
6. $\frac{x^{4}}{4}+\frac{y^{2}}{9}=1$.
7. $x^{2}-y^{2}=0$.
8. $4 x^{2}-y^{2}=0$.
9. $\frac{y-1}{y-2}=5^{\frac{1}{x-1}}$
(cf. Ex. 8, p. 8.)
10. The locus of an equation remains unchanged: (a) by any transposition of the terms of the equation; and $(\beta)$ by multiplying both members of the equation by any finite constant.
(a) If in any equation the terms are transposed from one member to the other in any way whatever, the locus of the equation is not changed thereby ; for the coördinates of all the points which satisfied the equation in its original form, and only those coördinates, satisfy it after the transpositions are made. [See Art. 35 (1).]
( $\beta$ ) If both members of an equation are multiplied by any finite constant $k$, its locus is not changed thereby. For if the terms of the equation, after the multiplication has been performed, are all transposed to the first member, that member may be written as the product of the constant $k$ and a
factor containing the variables. This product will vanish if, and only if, its second factor vanishes; but this factor will vanish if, and only if, the variables which it contalus are the comblinates of points on the locus of the original equation. Hence the coordinates of all points on the locas of the original equation, and only those courdinates, satisfy the equation after it has been multiplied by $k$; henee the locus remains unchanged if its equation is multiplied by a finite constant.
11. Points of intersection of two loci. Since the points of intersection of two loci are points on each locus, therefore the cobrdinates of these points must satisfy each of the two equations ; moreover, the coordiuates of no other jwints can satisfy both equations. Hence, wh find the coordinates of the prints of intersection of two curves, it is only necessary to regard their equations as simultaneous and solve for the coürdinates.
E.g., Find the courdinates of the points of intersection, $P_{1}$ and $P_{p}$ of the loci of $x-2 y=0$, and $y^{2}=z$. The point of intersection $P_{1}=\left(x_{p}, y_{1}\right)$ Is on loth curves,

$$
\therefore x_{1}-2 y_{1}=0 \text {, and } y_{1}^{2}=x_{1}{ }^{\circ}
$$

Solving these two equations,

$$
x_{1}=0 \text {, or } 4 \text {, and } y_{1}=0 \text {, or } 2 ;
$$

i.e., $P_{1}=(6,2)$ and $P_{2}=(0,9)$ are two points, the coordinates of which ratisly each of the two given equaLimas; therefore thiey are the points of iatersection of the loci of these equations.

## EXERCIBES

Find the points of intersection of the fullowing pairs of curves:

1. $: \begin{aligned} & 7 x-11 y+1=0 \\ & z+y-2=0\end{aligned}$
2. $\begin{array}{r}1 x+y=3, \\ 1 x-y=3 .\end{array}$

[^5]
13. Trace carefully the above loci; by measurement, find the coördinates of the points in which each pair intersect; and compare these results with those already obtained by computation.
40. Product of two or more equations. Given two or more equations with their second members zero;* the product of their first members, equated to zero, has for its locus the combined loci of the given equations.

This follows at once from the fundamental relation between an equation and its locus (see Art. 35 (1)), for the new equation is satisfied by the coördinates of those points which make one of its factors zero, but it is satisfied by the coördinates of no other points ; i.e., this new equation is satisfied by the coördinates of points that lie on one or another of the loci of the given equations.

The following example illustrates this principle in the case of two given equations.

Let the given equations be :

$$
\begin{equation*}
x+y=0 \quad . \quad . \quad . \quad(1) \text { and } x-y=0 \tag{2}
\end{equation*}
$$

[^6]Equation (1) represents the straight line $\mathcal{C D}$, and equation (2) the line $A B$, -bisecting respectively the angles between the axes. It is to be shown that the equation

$$
(x+y)(x-y)=0 \text {. . . (8) }
$$

(or, what is the same, $x^{2}-y^{2}=0$ ). formed from equations (1) and (2),

Fio. 8 . has for its locus both these lines.

Proof. If $P_{1} \equiv\left(x_{1}, y_{1}\right)$ is any point on $C D$, then its coordinates satisfy equation (1), hence $x_{1}+y_{1}=0$, and therefore $\left(x_{1}+y_{1}\right)\left(x_{1}-y_{1}\right)=0$; which shows that $P_{1}$ is a point of the locus of equation (3). But since $P_{1}$ was any point of CD, therefore the coorrdinates of every point on CDD satisfy equation (3); i.e., all points of $C D$ belong to the locus of equation (3).

In the same way it is shown that $A B$ belongs to the locus of equation (8).

Moreover, if $P_{8} \equiv\left(x_{3}, y_{8}\right)$ be any point not on $A B$ nor on $C D$, then $x_{3}+y_{3} \neq 0$, and $x_{3}-y_{8} \neq 0$, hence

$$
\left(x_{3}+y_{3}\right)\left(x_{3}-y_{3}\right) \neq 0 ;
$$

i.e., $P_{\mathrm{a}}$ does not belong to the locus of equation (8).

Hence the locus of equation (3) contains the loci of equations (1) and (2), but contains no other points.

The above theorem may be stated briefly thus: if $u, v, w$, etc., be any functions of two variables, then the equation urw $\cdot \cdots=0$ has for its locus the combined loci of the equations $u=0, v=0, v=0$, ete.

Nots. When possibles factoring the first member of an equation, whose second member is zero, simplifies the work of finding the lucus of the given equation.

## EXERCISES

What loci are represented by the following equations?

1. $x y=0$.
2. $\frac{x^{2}}{4}-\frac{y^{2}}{9}=0$.
3. $3 x^{2}+2 x y-7 x=0$.
4. $5 x y^{2}-2 x^{2} y=0$.
5. $x^{2}-2 x+1=0$.
6. $\left(x^{2}+y^{2}-4\right)\left(y^{2}-4 x^{2}\right)=0$.
7. Locus represented by the sum of two equations. Suppose the equations

$$
\begin{equation*}
2 y-x=0 \quad . \quad . \quad(1), \text { and } y^{2}-x=0 \tag{2}
\end{equation*}
$$

are given. Their loci are respectively $A B$ and $D P_{2} P_{1} C$ (Art. 39), and it is required to find the locus of their sum;

Fia. 28. i.e., of $2 y-x+y^{2}-x=0$, or, what is the same thing, of $y^{2}+2 y-2 x=0$

The locus of this last equation passes through all the points in which $A B$ and $D P_{2} P_{1} C$ intersect each other. For let $P_{1} \equiv\left(x_{1}, y_{1}\right)$ be one of these points, then since $P_{1}$ lies on $A B$, its coördinates satisfy equation (1); i.e.,

$$
\begin{equation*}
2 y_{1}-x_{1}=0 \tag{4}
\end{equation*}
$$

and since $P_{1}$ lies on $D P_{2} P_{1} C$, its coördinates satisfy equa tions (2); i.e.,

$$
\begin{equation*}
y_{1}^{2}-x_{1}=0 ; \tag{5}
\end{equation*}
$$

therefore, by adding equations (4) and (5),

$$
\begin{equation*}
y_{1}^{2}+2 y_{1}-2 x_{1}=0 \tag{6}
\end{equation*}
$$

This last equation proves (Art. 35 (1)) that $P_{1} \equiv\left(x_{1}, y_{1}\right)$ is on the locus of equation (3); i.e., the locus of equation (3) passes through $P_{1} \equiv\left(x_{1}, y_{1}\right)$.

Similar reasoning would show that the locus of equation
(3) prasses through every other point in which the loci of equations (1) and (2) intersect each other

In precisely the same way it may be proved generally that the lorus of the sum of two equations passes through all the points in which the loci of the turo given equations intersect each other.

If either of the given equations (1) or (2) had been multi. plied by any constant factor before adding, the above reasoning would still have led to the same conclusion; in fact, this theorem may be briefly, and more generally, stated thus: if $u$ and $v$ are any functions of the two variables $x$ and $y$, and $k$ is any constant, then the locus of

$$
u+k v=0
$$

passes through every point of intersection of the loci of

$$
u=0 \text { and } v=0 .
$$

For, let the locus of the equation $u=0$ be the curve $A B C$, the locus of $v=0$ be the curve DEF, and let $P_{1}=\left(x_{1}, y_{1}\right)$ be any one of the points in which these curves intersect each other.

Then the equation

$$
u+k v=0
$$

is satisfied by the coorrdhnates of the point $P_{1} \equiv$ $\left(x_{1}, y_{1}\right)$, because if these
 coordinates be substituted for $x$ and $y$ in the functions $u$ and $v$ they must make both these functions separately equal to zero. Therefore the locus of $u+k v=0$ passes through every point in which the loci of $u=0$ and $v=0$ intersect each other.

## EXERCISES

1. Verify Art. 41 by first finding the coordinates of the points of intersection of the loci of equations (1) and (2), and then substituting these coordinates in equation (3).
2. Find the equation of a curve that passes through all the points in which the following pairs of curves intersect:

$$
\begin{array}{ll}
\text { (a) }\left\{\begin{array}{l}
x^{2}+y^{2}=2 \\
x^{2}+2 x+y^{2}=0
\end{array}\right\} & \text { (ß) }\left\{\begin{array}{l}
y=\sin x \\
y=2 \cos x
\end{array}\right\}
\end{array}
$$

3. Find the equation of a curve through all the points common to the following pairs of curves:

$$
\begin{array}{ll}
\text { (a) }\left\{\begin{array}{l}
x^{2}=4 y, \\
y^{2}=4 \\
x
\end{array}\right\} & \text { (ß) }\left\{\begin{array}{l}
\rho=2 \cos \theta \\
\rho \cos \theta=1
\end{array}\right\}
\end{array}
$$

Note. It is to be observed that the method given in Art. 39, for finding the point of intersection of two curves, is an application of the theorem of Art. 41. For the process of solving two simultanenus equations, at least one of which involves two variables, consists in combining them in such a way as to obtain two simple equations, each involving only one variable. Now each of these simple equations represents an elementary locus, - one or more straight lines parallel to the axes, if the coordinates are Cartesian; circles about the pole, or straight lines through the pole, if the coördinates are polar, - and these elementary loci determine, i.e., pass through, the points of intersection of the original loci. To determine the points of intersection, then, of two loci, the original loci are replaced by simpler ones passing through the same common points. E.g., the points of intersection of the loci of Art. 39,

$$
2 y-x=0 . . \quad .(1), \text { and } y^{2}=x, \quad . \quad \text {. (2) }
$$

are given by the equations

$$
\left(y^{2}-x\right)-(2 y-x)=0 \quad \text { and } \quad\left[(2 y)^{2}-x^{2}\right]-4\left(y^{2}-x\right)=0
$$

that is, by

$$
y^{2}-2 y=0, \quad \text { and } \quad x^{2}-4 x=0
$$

which may be written

$$
y(y-2)=0 . . .(3), \quad x(x-4)=0 . . . .(4)
$$

But the locus of equation (3) is a pair of straight lines parallel to the $x-a \times 18$, and the locus of equation ( $t$ ) is a pair of straight lines parallel to the $y$-axis; and these loci have the same points of intersection as the loci (1) and (2).

## EXAMPLES ON CHAPTER III

1. Are the points $(3,6),(4,6)$, and $(3,3)$ on the loerts of $3 x+2 y=25$ ?
2. In the proint $\left(\begin{array}{ll}a & a \\ g^{3} & 3\end{array}\right)$ on then loens of $4 x^{2}+9 y^{2}=2 a^{3}$ ?
3. The ordinute of a certain point on the locus of $x^{3}+y^{3}=25$ is 4 . what is its almeinsa? What is the ordinate if the alnelimes is as?

Find by the method of Art. 39 where the following loci cut the axes of $x$ and $y$.
4. $y=(x-2)(x-3)$.
5. $16 x^{3}+9 y^{3}=144$.
6. $x^{3}+0 x+y^{8}=4 y+3$.

Find by the method of Art. 39 where the following loci cut the polar axis (or initial line).
7. $\rho=4 \sin ^{8} \theta$.
8. $\rho^{2}=a^{2} \cos 2 \theta$.
9. The two loci $\frac{x^{3}}{4}-\frac{y^{3}}{9}=1, \frac{x^{2}}{4}+\frac{y^{2}}{9}=4$ intersect in four points; find the lengths of the sides and of the diagonals of the quadrilateral formed by these points.
10. A triangle is formed by the points of intersection of the luei of $x+y=a, x-2 y=4 a$, and $y-x+7 a=0$. Find its area.
11. Find the distance between the points of intersection of the curves $8 x-2 y+6=0$, and $x^{2}+y^{2}=9$.
12. Does the locus of $y^{2}=4 x$ internect the locus of $2 x+3 y+2=0$ ?
13. Does the locus of $x^{3}-4 y+4=0$ cut the locus of $x^{2}+y^{3}=1$ ?
14. For what values of $m$ will the curves $x^{3}+y^{3}=9$ and $y=18 x+m$ nont intersect? (cf. Art. 9.) Trace these curves.
15. For what value of $b$ will the curves $y^{3}=4 x$ and $y=x+b$ intersect in two distinct points? in two coincident points? in two imaginary points (i.en not intersect)?
16. Find those two values of $e$ for which the points of intersection of the curves $y=2 x+c$ and $x^{2}+y^{2}=25$ are coincident.
17. Find the equation of a curve which pasees through all the proints of intersection of $x^{2}+y^{3}=25$ and $y^{3}=4 x$. Test the carreetress of the revult ly finding the conirdinates of the points of intersection and suls stituting them in the equation just found.
18. Write an ecquation which shall represent the combined loci of (1), (2), and (3) of Art. 37.

Discuss and construct the loci of the equations:
19. $\left(x^{2}-y^{2}\right)(y-\tan x)=0$.
22. $y=x^{3}$.
25. $\rho^{2}=a^{2} \cos 2 \theta$.
20. $x^{2}-y^{2}=0$.
23. $y^{2}=x^{3}$.
26. $\rho=3 \theta$.
21. $x^{4}-y^{4}=0$.
24. $y=10^{2}$.
$27 \rho=a \sin 2 \theta$.
28. Show that the following pairs of curves intersect each other in two coincident points ; i.e., are tangent to each other.

$$
\begin{aligned}
& \text { (a) }\left\{\begin{array}{l}
y^{3}-10 x-6 y-31=0, \\
2 y-10 x=47
\end{array}\right\} \\
& \text { (B) }\left\{\begin{array}{l}
9 x^{2}-4 y^{2}+54 x-16 y+29=0, \\
15 x-8 y+11=0
\end{array}\right\}
\end{aligned}
$$

29. Find the points of intersection of the curves

$$
\frac{x^{2}}{25}+\frac{y^{2}}{9}=1 \text { and } \frac{x^{2}}{25}-\frac{y^{2}}{9}=1 .
$$

## CHAPTER IV

## the equation of a locus

42. The equation of a locus. The second fundamental problem of amalytic geometry is the reyerse of the first (of. Art. 31), and is usually more difficult. It is to find, for a given geometrie figure, or locus, the eorresponding equation, i.e., the equation which shall be satisfied by the conordinates of every point of the given locus, and which shall not be satisfied by the coordinates of any other point. The geometric figure may be given in two ways, viz. :
(1) As a figure with certain known properties ; and
(2) As the path of a point which moves under known conditions.

In the latter case the path is usually unknown, and the complete problem is, first to find the equation of the path, and then from this equation to find the properties of the curve. This last is the third problem mentioned in Art. 31.

The two ways by which a locus may be "given" correspond to the two conceptions of a locus mentioned in Art. 35, and they lead to somewhat different methods of ohtaining the equation. The first method may be exemplified clearly. and most simply, by first considering the familiar cases of the straight line and the circle.
43. Equation of straight line through two given points.* Let $P_{1} \equiv(3,2)$, and $P_{3} \equiv(12,5)$ be two given points ; and
let $P \equiv(x, y)$ be any other point on the line through $P_{1}$ and $P_{2}$.

Draw the ordinates $M_{1} P_{1}, M P$, and $M_{2} P_{2}$, and through $P_{1}$ draw $P_{1} N$ parallel to the $x$-axis, meeting $M P$ in $R$ and $M_{2} P_{2}$ in $R_{2}$.

The triangles $P_{1} R P$ and $P_{1} R_{2} P_{2}$ are similar, hence

$$
\frac{R P}{R_{2} P_{2}}=\frac{P_{1} R}{P_{1} R_{2}}, \text { i.e., } \frac{M P-M_{1} P_{1}}{M_{2} P_{2}-M_{1} P_{1}}=\frac{O M-O M_{1}}{O M_{2}-O M_{1}}
$$

Substituting for $M P, O M, M_{1} P_{1}, O M_{1}$, etc., their values, this equation becomes

$$
\frac{y-2}{5-2}=\frac{x-3}{12-3}
$$

which reduces to

$$
\begin{equation*}
3 y-x-3=0 \tag{1}
\end{equation*}
$$

This is the required equation of the straight line through $P_{1}$ and $P_{2}$, because it fulfills both the requirements of the definition [cf. Art. 35 (1)]; i.e., it is satisfied by the coördinates of any (i.e., of every) point of this line, because $x, y$ are the coördinates of any such point; and it is not satisfied by the coorrlinates of any point which is not on this line, because the corresponding constructions for such a point would not give similar triangles, and hence the proportions which led to this equation would not be true.

That equation (1) is not satisfied by the coürdinates of
any point not on the line through $P_{1}$ and $P_{2}$ masy also be seen as follows :
let $\quad P_{8}=\left(x_{3}, y_{8}\right)$
be any point not on the line through $P_{1}$ and $P_{3}$, the ordinate $M_{3} P_{3}$ will meet $P_{1} P_{9}$ in some point
 $P_{6}=\left(x_{6}, y_{6}\right)$, for which $x_{4}=x_{3}$ but $y_{4} \neq y_{3}$. Since $P_{4}$ is on the line $P_{1} P_{2}$, its coordinates satisfy equation (1), therefore

$$
\begin{aligned}
& 8 y_{4}-x_{4}-8=0 \\
& \therefore 8 y_{3}-x_{3}-3 \neq 0 ; \quad\left[\text { since } x_{4}=x_{3} \text { and } y_{6} \neq y_{8}\right]
\end{aligned}
$$

hence the coordinates of $P_{3}$ do not satisfy the equation

$$
3 y-x=3 .
$$

44. Equation of straight line passing through given point and in given direction. $\dagger$ Let $P_{1} \equiv(5,4)$ be the given point, let the given line through $P_{1}$ make an angle of $30^{\circ}$ with the $x$-axis, and let $P \equiv(x, y)$ be any other point on this line.

Draw the ordinates $M_{1} P_{1}$ and $M P$, and through $P_{1}$ draw $P_{1} / R$ parallel to the $x$-axis to meot $M P$ ' in $R$. Then

$$
\tan R P_{1} P=\frac{R P}{P_{1} R}=\frac{M P-M_{1} P_{1}}{O M-O M_{1}}
$$

[^7]Substituting for $M_{1} P_{1}, M P, O M_{1}, O M$, and angle $R P_{1} P$ their values, and remembering that $\tan 30^{\circ}=\frac{1}{\sqrt{3}}=\frac{1}{8} \sqrt{3}$, this equation becomes

$$
\frac{1}{8} \sqrt{3}=\frac{y-4}{x-5} ; \text { i.e., } x-\sqrt{3} y-5+4 \sqrt{3}=0 .
$$

The equation just found is satisfied by the coördinates of any point on the given line, but is not satisfied by the coördinates of any point that is not on this line (cf. Art. 43); hence it is the equation of the line (cf. Art. 35).
45. Equation of a circle; polar coördinates $\dagger$ In deriving this equation, let polar coördinates be employed, merely for variety, and let the pole be taken

Fic. 31. on the circumference, with a diameter $O A$ extended for the initial line. Let $P \equiv(\rho, \theta)$ be any point on the circle, $\ddagger$ and let $r$ be the radius of the circle.

Connect $\boldsymbol{P}$ and $\boldsymbol{A}$ by a straight

[^8]line; then, in triangle $A O P$, angle $O P^{\prime} A$ is a right angle, $A O P=\theta, O P=\rho$, and $O P: O A=\cos \theta$; i.e.,
\[

$$
\begin{align*}
\rho: 2 r & =\cos \theta ; \\
\rho & =2 r \cos \theta . \tag{1}
\end{align*}
$$
\]

Equation (1) is satisfied by the polar eoborinates of every point on the circle; but is not satisfied by the colirdimates of a proint $Q$ not on the circle, since angle $A Q O$ is not a right angle. Therefore Eq. (1) is the equation of this circle (of. Ast. 35).

## EXERCISES

2. Fiad the equation of the straight line through the two points (1,7) and $(0,11)$; through the points $(-2,5)$ and $(3,5)$. Which is the pesstive side of each line?
3. Find the equation of the straight line through the tao points $(2,3)$ and $(-2,-3)$. Through what other point doess this line pass? Does the equation show this fact?
4. Find the equation of the straight line through the point $(5,-7)$, and making an angle of $45^{\circ}$ with the $x$-axis; making the angle $-45^{\circ}$ with the maxis.
5. Find the equation of the line through the paint ( $-6,-2$ ), and making the angle $150^{\circ}$ with the $x$-axis.
6. Construct the circle whose equation is $\rho=10 \cos \theta$.
7. With rectangular conordinates, find the equation of the circle of ralius 5, which pasass through the origin, and has its center on the saris. Is its prositive sile ontside or iuside?
8. Equation of locus traced by a moving point. In the problems given above, the geometric figure in each case was completely known ; and, in obtaining its equation, use was made of the known properties of similar triangles, triangles inseribed in a semicirele, and trigonometric functions. In only a few cases, however, is the curve so completely known ; in a large class of important problems, the curve

[^9]is known merely as the path traced by a point which moves under given conditions or laws. Such a curve, for instance, is the path of a cannon ball, or other projectile, moving under the influence of a known initial force and the force of gravity. Another such curve is that in which iron filings arrange themselves when acted upon by known magnetic forces. The orbits of the planets and other astronomical bodies, acting under the influence of certain centers of force, are important examples of this class of "given loci."

In such problems as these, the method used in Arts. 43 to 45, cannot, in general, be applied. A method that can often be enployed, after the construction of an appropriate figure, is:
(1) From the figure, express the known law, under which the point moves, by means of an equation involving geometric magnitudes; this equation may be called the "geometric equation."
(2) Replace each geometric magnitude by its equivalent algebraic value, expressed in terms of the coördinates of the moving point and given constants; then simplify this algebraic equation, and the result is the desired equation of the locus.
47. Equation of a circle: second method. To illustrate this second method of finding the equation of a locus, con-
sider the circle as the path traced by a
 point which moves so that it is always at a given constant distance from a fixed point. From this definition, find its equation.

Let $C \equiv(3,2)$ be the given fixed point, and let $P \equiv(x, y)$ be a point that moves so as to be always at the distance $2 \frac{1}{2}$ from $C$. Then

but

$$
C P=\sqrt{(x-3)^{2}+(y-2)^{3}} \quad(\text { Art. } 26,[2]) .
$$

$$
\therefore \sqrt{(x-0)^{2}+(y-2)^{2}}=\frac{1}{2} \quad \text { [algebraio equation] }
$$

i.e., $(x-3)^{2}+(y-9)^{2}=\frac{2 a}{3} ;$
hence

$$
4 x^{2}+4 y^{2}-24 x-16 y+27=0
$$

which is the required equation.
The locus of this equation can now be plotted by the methods of Art. 37, and its form and limatations can be discussed as is there done for other equations.

## EXERCISES

1. Find the equation of the path traced by a point which moves no that it is always at the distance 4 from the point $(5,0)$. Trace the locus.
2. Find the equation of the prath traced by a point which moves so that it is always equidistant from the points $(-2,3)$ and (7, 5) (ef. Ex. 0, p. 3).
3. A line is 3 units long; one end is at the point ( $-2,3$ ). Final the lucus of the other end (ef. Ex. 8, p. 34).
4. A point moves so as to be always equidistant from the $y$-axis and from the point (4,0). Find the equation of its path, and then trace and discuss the locus from its equation.
5. A point moves so that the sum of its distances from the two proints ( $0, \sqrt{5}$ ), $(0,-\sqrt{5})$ is always equal to 6 . Find the equation of the locus traced by this moving point.
6. A point moves so that the differnce of its dintances from the fwo points $(0, \sqrt{5}),(0,-\sqrt{5})$ is always equal to 2. Find the equation of the locus traced by this moving point.
7. The conic sections. Of the innumerable loci which may be given by means of the law governing the motion of the generating or tracing point, there is one class of partienlar importance; and it is to the study of this important class that the following pages will be chiefly devoted. These curves are traced by a point which moves so that its distance
from a fixed point aluays bears a constant ratio to its distance from a fixed atraight line. These curves are called the Conic Sections, or more briefly Conics, because they can be obtained as the curves of intersection of planes and right circular cones; * in fact, it was in this way that they first became known. The last three examples just given belong to this class, although it is only in No. 4 that this fact is directly stated. These loci are the parabola, the ellipse, and the hyperbola; it will be shown later that they include as special cases the straight line and the circle.t They are of primary importance in astronomy, where it is found that the orbit of a heavenly body is a curve of this kind.

The general equation, which includes all of these curves, will now be derived, and the locus briefly discussed; in a subsequent chapter will be given a detailed study of the properties of these curves in their several special forms.
(a) The equation of the locus. Let $F$ be the fixed point, - the focus of the curve; $D^{\prime} D$ the fixed

| ${ }^{Y}$ |  |
| :---: | :---: |
| D |  |
| $L$ | $L$ |
|  | $F$ |
| D' | Fic.33. | line,-the directrix of the curve; and $e$ the given ratio, - the eccentricity of the curve.

The coördinate axes may of course be chosen as is most convenient. Let $D^{\prime} D$ be the $y$-axis, and the perpendicular to it through $F$, i.e., the line OFX. be the $x$-axis. Let $P \equiv(x, y)$ be any position of the generating point, and let $O F$, the fixed distance of the focus from the directrix, be denoted by $k$; then the coördinates of the focus are $(k, 0)$. Connect $\boldsymbol{F}$ and $P$, and through $P$ draw L. $P$ perpendicular to the directrix.

Then $F P: L P=e, \quad$ [geometric equation]
but

$$
P P=\sqrt{(x-k)^{2}+y^{2}} \quad \text { (ArL 26). }
$$

and

$$
L P=x, \quad \text { [algeloraie equivaleuts] }
$$

henve
i.e.

$$
\begin{gather*}
\sqrt{(x-k)^{2}+y^{2}}=e x \\
\left(1-e^{2}\right) x^{2}+y^{2}-2 k x+k^{3}=0 \tag{1}
\end{gather*}
$$

which is the equation of the given locus.
This equation is of the second degree; in a later chapter it will be shown that every equation of the recond slegree between two variables represents a conie section. On thas areount it is often spoken of as the "second degree curve."

## (b) Discussion of equation (1).

If $x=0$, then $y= \pm k \sqrt{-1}$, which shows that this curve dues not intersect the $y$-axis as here chosen; i.e., a conic dues not intersect its directrix.

$$
\text { If } y=0 \text {, then }\left(1-r^{2}\right) x^{2}-2 k x+k^{2}=0
$$

whence

$$
\begin{equation*}
x=\frac{k}{1+e}, \text { or } x=\frac{k}{1-e}, \quad . \quad . \tag{2}
\end{equation*}
$$

i.e., a conic meets the line drawn through the focus and perpendicular to the directrix (the $x$-axis as here chosen) in two points whose distances from the directrix are $\frac{k}{1+e}$ and $\frac{k}{1-e}$ respectively; these points are called the vertices of the conic.

Equation (1) shows that for every value of $x$, the two corresponding values of $y$ are numerically equal but of upposite signs, hence the conic is symmetrical with regard ti) the $x$-axis as here chosen. For this reason the line drawn through the focus of a conic and perpendicular to the directrix is called the principal axis of the conic.

The form of the locus of equation (1) depends upon the value of the eccentricity, $e$; if $e=1$, the conic is called a
parabola; if $e<1$, an ellipse ; and if $e>1$, an hyperbola. Each of these cases will now be separately considered.
(1) The parabola, $e=1$. If $e=1$, then $F P: L P=1$, i.e., $F P=L P$ for every position of

Fic.34. the tracing point,* hence the curve passes through $A$, - the point midway between $O$ and $F$, - but does not again cross the principal axis (ef. also equations (2), above).

Moreover, when $e=1$, equation (1) becomes

$$
\begin{gather*}
y^{2}-2 k x+k^{2}=0 \\
y^{2}=2 k\left(x-\frac{k}{2}\right) \tag{3}
\end{gather*}
$$

which is the equation of the parabola, the coördinate axes being the principal axis of the curve and the directrix. Equation (3) shows that there is no point of this parabola for which $x<\frac{k}{2}$, and also that $y$ changes from 0 to $\pm \infty$ when $x$ increases from $\frac{k}{2}$ to $\infty$; hence the parabola recedes indefinitely from both axes in the first and fourth quadrants. Its form is given in Fig. 34.
(2) The ellipse, $e<1$. Equation (1) may be written in the form

$$
\begin{equation*}
y^{2}=\left(1-e^{2}\right)\left(\frac{k}{1-e}-x\right)\left(x-\frac{k}{1+e}\right), \cdots \tag{4}
\end{equation*}
$$

[^10]which shows, e being lews than 1, that $y$ is imaginary for all values of $x$ except those which satisfy the coudition
$$
\frac{k}{1+e}<x=\frac{k}{1-e}
$$
hence the ellipse lies wholly on the positive side of its directrix, and between two lines which are parallel to the directrix

and distant from it $\frac{k}{1+e}$ and $\frac{k}{1-e}$ respectively. Equation (4) shows that as $x$ increases from $\frac{k}{1+e}$ to $\frac{k}{1-e}, y$
ellipme. E.g., let $x=O M$; then the factors $\left(x-\frac{k}{1+k}\right)$ and $\left(\frac{k}{1-e}-z\right)$ are the two segments $A M$ and $M A^{\prime}$ of the line d $A^{\prime}$, and geometrically their product equals the square of the ordinate MQ of the wemicircle of which $A A^{\prime}$ is the diameter. If now the point $P$ on $M Q$ be so constructed

that $M P=\sqrt{1-e} \cdot M Q$, then $P$ is a point on the ellipwe whose equation is (4) above.

Similarly, any number of points on the curve can be constructed. This methot strows also that the ordinates of an ellipee are less than, but in a constant ratio to, the eorrempending andinates of the circle of which the dimmeter is the line joining the vertices of the ellipse. See also Note B, Appendix.
increases from 0 to $\frac{e k}{\sqrt{1-e^{2}}}$ (which value it reaches when $\left.x=\frac{k}{1-e^{2}}\right)$ and then decreases again to 0 . The form of the curve is therefore as shown in Fig. 35, where $O F=k$, $O A=\frac{k}{1+e}, O C=\frac{k}{1-e^{2}}, O A^{\prime}=\frac{k}{1-e}$, and $C B=\frac{e k}{\sqrt{1-e^{2}}}$.
(3) The hyperbola, $e>1$. Equation (1) may also be written in the form

$$
\begin{equation*}
y^{2}=\left(e^{2}-1\right)\left(x-\frac{k}{1+e}\right)\left(x-\frac{k}{1-e}\right), \tag{5}
\end{equation*}
$$

which, when $e>1$, shows that $y$ is imaginary for all values of $x$ between $x=\frac{k}{1+e}$ and $x=\frac{k}{1-e}$, and that $y$ is real for all other values of $x$. Equation (5) also shows that, as $x$

increases from $\frac{k}{1+e}$ to $\infty, y$ changes from 0 to $\pm \infty$, and that, as $x$ decreases from $\frac{k}{1-e}$ to $-\infty, y$ changes from 0 to $\pm \infty$. The form of the curve is therefore as shown in Fig. 37, where $O A=\frac{k}{1+e}$ and $O A^{\prime}=\frac{k}{1-e}=-\frac{k}{e-1}$.

Although these three curves differ so widely in form, they are really very closely related as will be further shown in Chap. XII, and in Note D of the Appendix.
49. The use of curves in applied mathematics. In Chap. ter III it was shown that whenever the relation between iwo variables, whose values depend upon each other, can be definitely stated, i.e., when the variables can be eonnected by an equation, then the geometric or graphie representation of this relation is given by means of a curve. Such a curse often gives at a glance, information which would otherwise require considerable computation to secure; and in many cases it brings out facts of peculiar interest and importance which might otherwise escupe notice.

The use of graphie methods in the study of physics and engineering, as well as in statistics and many other branches of investigation, is already extensive and is rapidly increasing. Under the name "graphie methods" there are included, however, not only such examples as those already given, where the equation comnecting the variables is known, but also those where no such equation can be found ; in these latter cases the curves constitute almost the only practical way of studying the relations involved.

As a simple example of this kind, suppose the temperature of a patient to be accurately observed at intervals of one hour; if the numbers representing the hours, i.e., 1, 2, 3, $\cdots$ are taken as abscissas, and the corresponding numerical values of the temperatures be taken as ordinates, then a smooth curve drawn through the points so determined will express graphically the variation of the temperature of this patient with the time. This curve will also show to the physician what was the greatest and least temperature during the interval of the observations, as well as the time when each of

[^11]these was attained. In this problem the curve gives no new information, but it presents in a much more concise and forcible form the information given by the tabulated numbers.

Again, if the distances passed over by a train in successive minutes during the run between two stations are taken as ordinates, and the corresponding number of minutes since starting, as abscissas, a smooth curve drawn through the points so determined will show at a glance, to an experienced eye, where and when additional steam was turned into the cylinders, brakes applied, heavy grades encountered, etc., etc.

In all such cases the coördinates of the points are taken to represent the numerical values of related quantities, such as time, length, weight, velocity, current, temperature, etc., and the curve through the points so determined usually gives, to an experienced person, all the information concerning the relations involved that is of practical importance. It is in the study of such curves that much of the value of training in analytic geometry becomes apparent to the physicist and the engineer. The student should early learn to translate physical laws into graphic forms, and he should give careful attention to the interpretation of all changes of form, intercepts, intersections, etc., of such curves.

## EXERCISES

1. In simple interest if $p \equiv$ principal, $t \equiv$ time, $r \equiv \mathrm{rate}$, and $a \equiv$ amount, then $a=p(1+r t)$. If now particular numerical values are given to $p$ and $r$, and if the values of the variable $a$ be taken as ordinates, and the corresponding values of $t$ as abscissas, then the locus of this equation may be drawn. Draw this locus. What line in the figure represents the principal? What feature of the curve depends upon the rate der cent? Interpret the intercepts on the axes.
2. Five to $p$ and $r$ in exercise I different values and, with the same ases, draw the cor reopronding locus. How do those loct differ? What dones their puint of intersection tmean?
3. With the same axes as tefore draw the curve for which interest amd fime are the courdinates; how is it related to the curves of exerciens 1 and 2 ?
4. Draw and discuas the curve showing the relation between amownt, principal, rate, and time in the case of compround interest.
(a) When interest is comprounded aunually.
( $\beta$ ) When interest is compounded quarterly.
(y) When interest is compounded instantaneously.
5. A wage earner has already leven working 10 days at 81. in por day, and continues to do so 20 days longer, after which he is idle during 5 days; bee then works 14 days more at the same wages, after which his employer raises his wages to ge.ion per day for the next 20 dars: using the amountes carned as ordinates, and the time (in days) as abscissas, draw carefully the broken line which states the above facts.

What modification of the drawing would be necossary to show that the wage earner forfeited 50 cents per day during his idleness?
6. The following table shows the production of steel in Great Britain and the Cnited States from 18.8 to 1891 .

|  | U. 8. | ©.B. |  | 0.8. | O.8. |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1878. | $\begin{aligned} & 7.3 \text { (100,000 } \\ & \quad \text { long tons) } \end{aligned}$ | $\begin{gathered} 10.6(100,(600 \\ \text { long tons) } \end{gathered}$ | 1885 . . | 17.1 | 10.7 |
| 1878. | 9.3 | 10.9 | 1886 : | 25.3 | 23.4 |
| 1980. | 12.5 | 13.7 | 188\% . . | 33.4 | 31.5 |
| 1881 . . | 15.9 | 18.6 | 1888. | 29.9 | 34.0 |
| 1582 . | 17.4 | 21.8 | 1859 . . | 33.8 | \$6.7 |
| 1583. | 16.7 | 20.8 | 1890. | 42.8 | 86.8 |
| 1884 . . | 15.5 | 18.5 | 1891 . . | 39.0 | 32.5 |

Tsing time (in years) as abscisens, and quantity of steel produced ( 100,000 tons per unit) as ordinates, the separate points represented by

[^12]the table have been plotted（Fig．38）and then joined by straight lines， dutted for Great Britain and full for the United States．＊

Interpret fully the figure．

7．Exhibit graphically the information contained in the following table on the expense of moving freight per＂ton－mile＂on N．Y．C．\＆ H．R．R．R．from 1866 to 1893.

| 1866 | $2.16 申$ | 1873 | $1.03 q$ | 1880 | $.54 申$ | 1887 | ．5f申 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 1867 | 1.95 | 1874 | .98 | 1881 | .56 | 1888 | .59 |
| 1888 | 1.80 | 1875 | .90 | 1882 | .60 | 1889 | .57 |
| 1869 | 1.40 | 1876 | .71 | 1883 | .68 | 1890 | .54 |
| 1870 | 1.15 | 1877 | .70 | 1884 | .02 | 1891 | .57 |
| 1871 | 1.01 | 1878 | .60 | 1885 | .54 | 1892 | .54 |
| 1872 | 1.13 | 1879 | .55 | 1886 | .53 | 1893 | .54 |

8．The following table gives the population of the countries named between 1810 and $1896: \dagger$
－In the figure the linear unit on the $x$－axis is 5 times as long as the linear unit on the $y$－axis．It will，however，be noticed that the essential feature of a system of coördinates，the＂one－to－one correspondence＂of the symbol （ $x, y$ ）and the points of a plane，is not disturbed by using different scales for ordinates and abscissas．
$\uparrow$ The authors are indebted to Professor W．F．Willcox of Cornell Univer－ sity for these data，which are compiled from the Sutesman＇s Year Book for 1897，and from Statistik des Deutschen Reichs，Bd．44， 1892.

## EXAMPLES ON CMAPTER IV

1. Find the equations of the sides of the triangle whose vertims are the peotints ( 2,3 ), $(1,-5),(3,-5)$ (el Art. 43). Test the rewulting equations by substitution of the given coordinates.
2. Find the equations of the sides of the mpuare whome vertioss are $(0,-1),(2,1),(0,3),(-2,1)$. Compare the equations of the paralle:1 sides; of perpendicular sides.
3. Find the ceprrdimates of the center of the square in N.x. 2. Then fiad the radius of the circumscribed circle, and (Art. 17) the equation of that circle. Test the rosult by finding the coordinates of the points of fritermetton of one of the aides with circte (Art. 30).
4. Find the equation of the path traced by a print which is always equidistant from the pointa
(a) $(2,0)$ and $(0,-2)$; ( $\beta$ ) ( 3,2 ) and ( $8, \beta)$;
(y) $(a+b, a-b)$ and $(a-b, a+b)$.
5. A point moves so that its ordinate always exceeds of of its almeima by 6. Find the equation of its locus, and trace the curve.
6. A point moves so that the square of its ordinate is always 4 times ita ahseissa. Find the equation of its locus and trace the curve.
7. Finl the equation of the locus of a print which moves so that the sum of its distances from the points $(1,3)$ and $(4,2)$ is always 5 . Trace and discuss the curve.
8. Find the equation of the locus of the point in example 7 , if the difference of its distances from the fixed $[$ wints is always 2 .
9. Express by a single equation the fact that a pwint moves so that its dintance from the s-axis is always numerically 3 times its distance Irom the g-axis.
10. A proint moves sn that the square of its distance from the pwint $(a, 0)$ is 4 times its ordinate. Find the equation of its locus, and trace the curve.
11. A pmint moves so that its distance from the $x$-nxis is $\frac{1}{3}$ of its distance from the origin. Find the equation of its locus, and trace the eurre.
12. A print moves so that the difference of the squares of its distanes from the prints $(1,3)$ and $(8,2)$ is 5 . Find the equation of its loctes and trace the curve.
13. Solve example 12 if the word "sum" is substituted for "difference."
14. Let $A \equiv(a, 0), B \equiv(b, 0)$, and $A^{\prime} \equiv(-a, 0)$ be three fixed points; find the equation of the locus of the point $P \equiv(x, y)$ which moves so that $\overline{P B}^{3}+\overline{P A}^{2}=2 \overline{P A^{3}}$.
15. A point moves so that $\}$ of its abscissa exceeds $\frac{f}{}$ of its ordinato by 1. Find the equation of its locus and trace the curve.
16. Find the equation of the locus of a point that is always equidistant from the points $(-3,4)$ and $(5,3)$; from the points $(-3,4)$ and $(2,0)$. By means of these two equations find the coüdinates of the $p^{\text {roint that is equidistant from the three given points. }}$
17. Let $A \equiv(-1,3), B \equiv(-3,-3), C \equiv(1,2), D \equiv(2,2)$ be four fixed points, and let $P \equiv(x, y)$ be a point that moves subject to the condition that the triangles $P A B$ and $P C D$ are always equal in area; find the equation of the locus of $P$.
18. If the area of a triangle is 25 and two of its vertices are $(5,-6)$ and $(-3,4)$, find the equation of the locus of the third vertex.
19. A point moves so that its distance from the pole is numerically equal to the tangent of the angle which the straight line joining it to the origin makes with the initial line. Find the polar equation of its locus and plot the figure.

## CHAPTER V

## THE STRAIGHT LINE. EQUATION OF FIRST DEGREE $A x+B y+C=0$

50. In Chapter III it was shown that to every equation between two variables there corresponds a definite geometric locus, and in Chapter IV it was shown that if the geometrie locus be given, its equation may be found. It still remains to exhihit in greater detail some of the more elementary loci and their equations, and to apply amalytic methods to the study of the properties of these curves. Since the straight line is a simple locus, and one whose properties are already well understood by the student, its equation will be examined first.

In studying the straight line, as well as the circle and other second degree curves, to be taken up in later chapters, it will be found best first to obtain the simplest equation which represents the loous, and to study the properties of the curve from that simple or standard equation. Then it remains to find methods for reducing to this standard form any other equation that represents the same locus.

## 51. Equation of straight line through two given points. A

 numerical example of the equation of the line through two fixal points has already been given in Art. 43; in the present article the equation of a straight line through any two given points will be derived; the method, however, will be precisely the same as that already employed in the numerical example.Let the two given fixed points be $P_{1} \equiv\left(x_{1}, y_{1}\right)$ and $P_{2} \equiv$ ( $x_{2}, y_{2}$ ), and let $P \equiv(x, y)$ be any other point on the line through $P_{1}$ and $P_{2}$. Draw the ordinates $M_{1} P_{1}, M_{2} P_{2}$ and

$M P$; also through $P_{1}$ draw $P_{1} R_{2}$ parallel to the $x$-axis, and meeting $M P$ in $R$ and $M_{2} P_{2}$ in $R_{2}$. Then the triangles $P_{1} R P$ and $P_{1} R_{2} P_{2}$ are similar ;
$\therefore \quad \frac{R P}{R_{2} P_{2}}=\frac{P_{1} R}{P_{1} R_{2}}$, i.e., $\frac{M P-M_{1} P_{1}}{M_{2} P_{2}-M_{1} P_{1}}=\frac{O M-O M_{1}}{O M_{2}-O M_{1}}$.
Substituting in this last equation the coürdinates of $P_{1}$ $P_{2}$, and $P$, it becomes

$$
\begin{equation*}
\frac{y-y_{1}}{y_{2}-y_{1}}=\frac{x-x_{1}}{x_{2}-x_{1}} \tag{9}
\end{equation*}
$$

and since $P \equiv(x, y)$ is any point on the line through $P_{1}$ and $P_{2}$, therefore equation [9] is satisfied by the coördinates of every point on this line. That equation [9] is not satisfied by the coördinates of any point except such as are on the line $P_{1} P_{2}$ may be proved as was done in Art. 43.

Equation [9] then fulfills both requirements of the definition in (1) of Art. 35, and is therefore the equation of the straight line through the two points $\left(x_{1}, y_{1}\right)$ and $\left(x_{2}, y_{2}\right)$. This equation will be frequently needed and will be referred to as a standard form; it should be committed to memory.*

[^13]52. Equation of straight line in terms of the intercepts which it makes on the coordinate axes. If the two given

points in Art. 51 are those in which the line cuts the axes of comrdinates, i.e., $A \equiv(a, 0)$ and $B \equiv(0, b)$ (Fig. 41), then equation [9] becomes
$$
\frac{y-0}{b-0}=\frac{x-a}{0-a}
$$
that is,
\[

$$
\begin{equation*}
\frac{x}{a}+\frac{y}{b}=1, \tag{10}
\end{equation*}
$$

\]

where $a$ and $b$ are the intercepts which the line cuts from the axes.

This is another standard form of the equation of the sraight line; it is known as the symmetrical or the intercept form.

Equation [10] may also be derived independently of equation [9] thus : let the line MN (Fig. 42), whose equation is to be found, cut the axes at the points $A \equiv(a, 0)$ and $B \equiv(0, b)$, and let $P \equiv(x, y)$ be any other point on this line. Connect $O$ and $P$; then

$$
\text { area } O P B+\text { area } O A P=\text { area } O A B
$$

Hat is,

$$
\frac{1}{2} b x+\frac{1}{2} a y=\frac{1}{2} a b,
$$

and, dividing by $\frac{1}{2} a b$, this equation becomes $\frac{x}{a}+\frac{y}{b}=1$, as alowe.

## EXERCISES

1. Show that equation [10] is now watisfied by the coordinates of any point except thoee lying on $M \mathcal{N}$.
2. Write down the equations of the lines through the following pairs of points:
(a) $(3,4)$ and $(5,2)$;
( $\gamma$ ) $(-6,1)$ and $(-2,-5)$;
( $\beta$ ) $(3,4)$ and $(5,-2)$;
( $\delta$ ) $(-15,-3)$ and $\left(\frac{8}{3}, \frac{-7}{9}\right)$.
3. Write the equations of the lines which make the following intercepts on the $x$ and $y$-axes respectively.
(a) 4 and 7 ; ( $\beta$ ) -3 and 5 ; ( $\gamma$ ) $\frac{4}{3}$ and $-\frac{1}{2}$; ( ( ) $-\frac{a}{2}$ and $3 a$.
4. What do equations [9] and [10] become if one of the given points is the origin?
5. By drawing, in Fig. 42, a perpendicular $P M$ from $P$ to the $x$-axis. derive equation [10] from the similar triangles MAP and OAB.
6. Is equation [10] true if $P$ is on $M N$ but not between $A$ and $B$ ?
7. Are equations [9] and [10] true if the coordinate axes are not at right angles to each other?
8. Is the point $\left(3,4 \frac{1}{2}\right)$ on the line throngh the points $(2,3)$ and $(5,7)$ ? On which side of this line is it? Which is the negative side of this line?
9. What intercepts does the line through the points $(1,-6)$ and $(-3,5)$ make on the axes ?
10. The vertices of a triangle are: $(4,-5),(2,3)$, and $(3,-6)$. Find the equations of the sides; also of the three medians; then find the coordinates of the point of intersection of two of these medians, and show that these coordinates satisfy the equation of the other median. What proposition of plane geometry is thus proved?
11. Find the tangent of the angle (the "slope," cf. Art. 27) which the line in exercise 9 makes with the $x$-axis.
12. Draw the line whose equation is $\frac{x}{2}+\frac{y}{3}=1$, and then find the equations of the two lines which pass through the origin and trisect that portion of this line which lies in the first quadrant.
13. Equation of straight line through a given point and in a given direction (cf. Art. 44). Let $P_{1} \equiv\left(x_{1}, y_{1}\right)$ be the given point, and let the direction of the line be given by the angle $X A P=\theta$ which the line makes with the $x$-axis; also let $P \equiv(x, y)$ be any point on the given line and denote the slope, i.e., $\tan \theta$, by $m$. Draw the ordinates
$M_{1} P_{1}$ and $M P$, and through $P_{1}$ draw $P_{1} R$ parallel to the $x$-axis and meeting the ordinate $M P$ in $R$.

Then, is triangle $R P_{1} P_{\text {. }}$ the angle $R P_{1} P=\theta$;

hence

$$
m=\tan \theta=\frac{R P}{P_{1} R}=\frac{y-y_{1}}{x-x_{1}}
$$

[Since $R P^{\prime}=y-y_{1}$ and $P_{1} R=x-x_{1}$ ];
that is,

$$
\begin{equation*}
y-y_{1}=m\left(x-x_{1}\right), \tag{11}
\end{equation*}
$$

Which is the desired equation.
Cor. If the given point be $B \equiv(0, b)$, i.e., the point in which the line meets the $y$-axis, then equation [11] becomes

$$
\begin{equation*}
y=m x+b \tag{12}
\end{equation*}
$$

Equation [12] is usually spoken of as the slope form of the equation of the straight line.

## EXERCISES

1. What do the constants $m$ and $b$ in equation [12] mean? Draw the line for which $m=4$ and $b=3$; also that for which $m=-1$ and $b=-1$.
2. What is the effect on the line [12] of a change in $b$ while $m$ remains the same? What if $m$ be changed and $b$ left unchanged?
3. Dascribe the effect on the line [11] of changing $m$ while $x_{1}$ and $y_{1}$ remain the same; also the effeet resulting from a change in $x_{1}$ while $m$ and $y_{1}$ remain the same.
4. Write the equation of a line through the point $(-3,7)$, and making with: the $x$-axis an angle of $30^{\circ}$; of -30 ; of $\left(\frac{2 \pi}{3}\right)^{(1)}$; of $\left(\frac{7 \pi}{6}\right)^{10}$.
5. Write the equations of the following lines:
(a) slope $3, y$-intercept b; ( $\bar{\beta}$ ) slope 1. $y$-intercept -3 ;
(y) slope -2 , yintercept -f.
6. A line has the slope 6; what is its $y$-intercept if it passes through the point ( 7,1 )?
7. What must be the slope of a line whose $y$-intercept is 3 , in order that it may pass through the point $(-5,5)$ ?
8. Is the point $(1,1)$ on the line passing through the point $(-2,-14)$, and making an angle $\tan ^{-1} \frac{1}{\gamma}$ with the $x$-axis?
9. How do the lines $y=3 x-1, y=3 x+7$, and $2 y-6 x+15=0$ differ from each other? What have they in common? Draw these lines.
10. What is common to the lines $y=3 x-1,2 y=5 x-2$, and $7 x-3 y=3$ ?
11. What is the slope of line [9]? of line [10]?
12. Derive equation [12] independently of equation [11].
13. Equation of straight line in terms of the perpendicular from the origin upon it, and the angle which that perpendicular makes with the $x$-axis. Let $H K$ be the line whose equation

is sought, and let the perpendicular ( $O N=p$ ) from $O$ upon this line, and the angle ( $a$ ) which this perpendicular makes with the $x$-axis, be given. Also let $P \equiv(x, y)$ be any point on $H K$; then by projection upon $O N$ (Art. 17),

$$
\begin{gather*}
O M \cos a+M P \sin a=O N, \\
x \cos a+y \sin a=p, \tag{18}
\end{gather*}
$$

i.e.,
which is the required equation.
Equation [13] is known as the normal form of the equation of the straight line.

In the following pages $p$ will always be regarded as positive, and $\boldsymbol{a}$ as positive and less than $360^{\circ}$.
55. Normal form of equation of straight line: second method. The stuilent should bear in mind that to get the equation of a curve, he has merely to obtain an equation that is satisfied by the coirdinates of every point on the curve, and not satisfieal by the coordinates of any other point ; and that it is wholly immaterial what partioular geometrie property he may employ in the accomplishment of this purpose. This fact is alrealy illustrated in Art. 52, where equation [10] was obtained in two ways, while Ex. 5, p. 84, gives still a third method by which the same equation may be found. So also it is possible to derive equation [13] by other trethols than that employed in Art. 54.*
E.g., in Fig. 41 draw a perpendicular from $O$ to the line $A B$, let its length be denoted by $p$, and let $a$ be the angle which it makes with the $x$-axis, then
whence

$$
\left.\begin{array}{rl}
a \cos a & =p, \text { and } b \sin \alpha \\
a & =\frac{p}{\cos a}, \quad \text { and } \quad b
\end{array}\right)=\frac{p}{\sin a} . ~ .
$$

Subatituting these values of $a$ and $b$ in equation [10], it becomes

$$
\frac{x}{\frac{p}{\cos \alpha}}+\frac{y}{\frac{p}{\sin \alpha}}=1 \text {, i.e., } x \cos \alpha+y \sin \alpha=p
$$

which is the form already derived in Art. 54.
Sors. In Art. 2, constants, variables, etc., were illustrated by means of a triangle. Now that the student has learned that the equation $\frac{1}{a}, y=1$. for example, represents a straight line, i.e., that this equation is satisfied by all those pairs of values of $x$ and $y$ which are the ceobrdinates of points on this line, a somewhat betier illustration can lee given. lhoth $x$ and $g$ are variables, but are not independent; each is an implieit function of the other. For any particular line a and bare constants, but they may represent other constants in the equation of another time, i.e. tiey are arbitrary constants, and are often called parameters of the lime.

[^14]
## EXERCISES

1. The perpendicular from the origin upon a certain line is 5 ; this perpendicular makes an angle of $\frac{\pi}{3}$ with the $x$-axis; what is the equation of the line?
2. If in equation [13] $p$ is increased while $\alpha$ remains the same, what is the effect upon the line? If a be changed while $p$ remains the same, what is the effect?
3. A certain line is 3 units distant from the origin, and makes an angle of $120^{\circ}$ with the $x$-axis; what is its equation?
4. Given $a=30^{\circ}$, what must be the length of $p$ in order that the lino $H K$ (see Fig. 44a) shall pass through the point $(7,2)$ ?
5. A line passes through the point $(-3,-4)$, and a perpendicular upon it from the origin makes an angle of $225^{\circ}$ with the $x$-axis. What is the equation of this line?
6. In Fig. $44 a$ draw through $M$ a line parallel to $H K$, meeting $O N$ in $R$; then draw through $P$ a perpendicular to $M R$, meeting it in $Q$; by means of the figure so constructed derive equation [13] anew.
7. Summary. The results of Arts. 51-55 may be briefly summarized thus:

The position of a straight line is determined by : (1) two points through which it passes; (2) one point and the direction in which the line passes through this point. Under (1) there is the special case in which the two given points are one on the $x$-axis and the other on the $y$-axis. Under (2) there are two special cases : (a) when the given point is on an axis (the $y$-axis say), and ( $\beta$ ) when the point is given by its distance and direction from the origin, while the line whose equation is sought is perpendicular to the line which connects the given point to the origin.

Corresponding to these two general and three special cases, there have been derived five standard forms of the equation of the straight line, viz.: equations [9], [10], [11], [12], and [13].

It may be remarked that equations [9] and [10] are independent of the angle between the coördinate axes, while [11],
[1:], and [18] (m, c, and $p$ retaining their present meanings) are true only when the axes are rectangular. It may also be prointed out that, from the nature of its derivation, equacion [9] is inapplicable when the line is parallel to either axis; equation [10] is inapplicable when the line passes through the origin ; and equations [11] and [12] are not applicable when the line is parallel to the $y$-axis.
57. Every equation of the first degree between two variables has for its locus a straight line. It will probably not have escaped the reader's notice that the five "standard" equathons (equations [9] to [13]) of the straight line, which have heen derived in Arts. 51 to 54 , are each of the first degree. It will now be shown that every equation of the first degree between two variables has a straight line for its locus. The most general equation of this kind may be written in the form

$$
\begin{equation*}
A x+B y+C=0 \tag{1}
\end{equation*}
$$

where $A, B$, and $C$ are constants, and neither $A$ nor $B$ is zero.*

Let $P_{1} \equiv\left(x_{1}, y_{1}\right), \quad P_{3} \equiv\left(x_{2}, y_{2}\right)$, and $P_{8} \equiv\left(x_{3}, y_{8}\right)$ be any three points on the locus of equation (1). Draw the ordinates $M_{1} P_{1}, M_{2} P_{8}$, and $M_{8} P_{8}$; also draw $\boldsymbol{H} P_{2}$ and $K P_{8}$ parallel to the $x$-axis.

Then, by Art. 85 (1),

$$
\begin{aligned}
& A x_{1}+B y_{1}+C=0 \ldots(2) \\
& A x_{2}+B y_{2}+C=0 \ldots(8) \\
& A x_{3}+B y_{3}+C=0 \ldots(4)
\end{aligned}
$$

[^15]By subtracting eq. (3) from eq. (2), and also eq. (4) from eq. (3), the two equations
and

$$
\begin{aligned}
& A\left(x_{1}-x_{2}\right)+B\left(y_{1}-y_{3}\right)=0, \\
& A\left(x_{2}-x_{8}\right)+B\left(y_{2}-y_{3}\right)=0,
\end{aligned}
$$

are obtained. These give

$$
\begin{equation*}
\frac{y_{1}-y_{2}}{x_{1}-x_{2}}=-\frac{A}{B}, \text { and } \frac{y_{2}-y_{3}}{x_{3}-x_{3}}=-\frac{A}{B} ; \tag{5}
\end{equation*}
$$

hence, $\frac{y_{1}-y_{2}}{x_{1}-x_{2}}=\frac{y_{2}-y_{3}}{x_{2}-x_{3}}$.
But $\quad y_{1}-y_{2}=H P_{1}, \quad x_{1}-x_{2}=-M_{1} M_{2}=-H P_{2}$.

$$
y_{2}-y_{3}=K P_{2}, \text { and } x_{2}-x_{8}=-M_{2} M_{3}=-K P_{8} ;
$$

hence, from eq. (6), $\quad \frac{H P_{1}}{H P_{2}}=\frac{K P_{2}}{K P_{8}}$.
Also, by construction,

$$
\angle P_{2} H P_{1}=\angle P_{3} K P_{2}
$$

hence, triangle $H P_{2} P_{1}$ is similar to triangle $K P_{8} P_{2}$,
and $\quad \angle P_{1} P_{2} H=\angle P_{2} P_{8} K$;
$\therefore \angle P_{1} P_{2} H+\angle H P_{2} K+\angle K P_{2} P_{3}$

$$
=\angle P_{2} P_{3} K+\angle P_{8} K P_{2}+\angle K P_{2} P_{3}=2 \mathrm{rt} . \triangle ;
$$

i.e., $P_{2}$ lies on the straight line joining $P_{1}$ and $P_{3}$. But, since $P_{2}$ is any point on the locus of $A x+B y+C=0$, hence all points of this locus lie on the same straight line $P_{1} P_{3}$. which, therefore, constitutes the locus of $A x+B y+C=0$.

Since this demonstration does not depend upon the angle $\omega$, therefore it applies whether the axes are oblique or reetangular; hence the theorem : every equation of the first degree between two variables, when interpreted in Cartesian coördinates, represents a straight line.*

[^16]Because of this fact, such an equation is often spopken of as a linear equation.

Nork. In the equation $A z+B y+C=0$, there are apparently three comstants; in reality, there are hut two independent constants vix. the ration of the coutficients (ef. Art. 36). This corresponds to the fact that a atraight fine is determined geometrically by two conditions.

## 58. Reduction of the general equation $A x+B y+C=O$ to

 the standard forms. Determination of $a, b, m, p$, and $a$ in terms of $\boldsymbol{A}, \boldsymbol{B}$, and $\boldsymbol{C}$. ${ }^{*}$(1) Reduction to the standard form $\frac{x}{4}+\frac{y}{6}=1$ (symmetric or intercepe form).

That the equation

$$
A x+B y+C=0
$$

represents some straight line has just been shown (Art. 57); again, since multiplication by a constant, and transposition, do not change the locus (Art. 38), therefore

$$
\begin{equation*}
\frac{x}{-\frac{C}{A}}+\frac{y}{-\frac{C}{B}}=1+ \tag{2}
\end{equation*}
$$

represents the same line. But equation (2) is in the required form (Art. 52), and its intercepts are :

$$
a=-\frac{C}{A}, \text { and } b=-\frac{C}{B}
$$

(2) Reduction to the standard form $y=m x+b$ (alope form).

[^17]The equation $A x+B y+C=0$ has the same locus as has the equation

$$
\begin{equation*}
y=\left(-\frac{A}{B}\right) x+\left(-\frac{C}{B}\right) * \quad \tag{3}
\end{equation*}
$$

(see Art. 38); but this is the equation (Art. 53) of a line drawn through the point $\left(0,-\frac{C}{B}\right)$, and making with the $x$-axis the angle $\theta=\tan ^{-1}\left(-\frac{A}{B}\right)$; hence equation (3) is in the required form, and

$$
m=-\frac{A}{B}, \text { and } b=-\frac{C}{B} .
$$

(3) Reduction to the standard form $x \cos \alpha+y \sin \alpha=p$ (normal form).

If equation (1) and

$$
\begin{equation*}
x \cos \alpha+y \sin \alpha=p \tag{4}
\end{equation*}
$$

represent the same line, then they differ merely by some constant multiplier, say $k$ (cf. Art. 38). Then

$$
\begin{aligned}
& k A x+k B y+k C \equiv x \cos \alpha+y \sin \alpha-p=0 ; \\
& \therefore k A=\cos \alpha, k B=\sin \alpha, \text { and } k C=-p ; \\
& \therefore k^{2} A^{2}+k^{2} B^{2}=\cos ^{2} \alpha+\sin ^{2} \alpha=1 ;
\end{aligned}
$$

whence

$$
k=\frac{1}{\sqrt{A^{2}+B^{2}}}
$$

hence

$$
\cos \alpha=\frac{A}{\sqrt{A^{2}+B^{2}}}, \sin \alpha=\frac{B}{\sqrt{A^{2}+B^{2}}}
$$

and

$$
p=-\frac{C}{\sqrt{A^{2}+B^{2}}}
$$

[^18]wherein the algebraic sign of $\sqrt{A^{3}+B^{3}}$ is to be chosen 80 as to make $\frac{-C}{\sqrt{A^{2}+13^{2}}}$ positive, since $p$ is to be always pmaitive (Art. 64); i.e., the sign of $\sqrt{A^{2}+1 B^{2}}$ is to be opposite to that of the number represented by $C$.

Hence, to reduce equation (1) to the normal form, i.e., to the form of equation (4), it is only necessary to diside equation (1) by $\sqrt{A^{2}+13^{2}}$, with the sign properly chosen, and transpose the constant term to the second member. This gives

$$
\frac{A}{\sqrt{A^{2}+B^{2}}} x+\frac{B}{\sqrt{A^{2}+B^{2}}} y=\frac{-C}{\sqrt{A^{2}+B^{2}}} .
$$

(4) Another method for reduction to the normal form.

If the equation $A x+B y+C=0$ and $x \cos a+y \sin a=p$ represent the same line, then they must have the same $y$-intereept and the same slope, i.e.,

$$
\begin{align*}
& -\frac{C}{B}=\frac{p}{\sin a}  \tag{5}\\
& -\frac{A}{B}=-\frac{\cos a}{\sin a} \tag{6}
\end{align*}
$$

Squaring eq. (6), and adding 1 to each member, gives

$$
\begin{aligned}
\begin{aligned}
\frac{A^{2}+B^{2}}{B^{2}} & =\frac{\cos ^{2} a+\sin ^{2} a}{\sin ^{2} a} \\
& =\frac{1}{\sin ^{2} a} ; \\
\therefore \sin a & =\frac{B}{\sqrt{A^{2}+B^{2}}} ; \\
\cos a & =\frac{A}{\sqrt{A^{2}+B^{2}}} \text { and } p=\frac{-C}{\sqrt{A^{2}+B^{2}}}
\end{aligned}
\end{aligned}
$$

whence
as before. These, then, are the values of $p, \sin a$, and $\cos a_{1}$ which are to be substituted in $x \cos a+y \sin a=p$.

Hence $\frac{A}{\sqrt{A^{2}+B^{2}}} x+\frac{B}{\sqrt{A^{2}+B^{2}}} y=-\frac{C}{\sqrt{A^{2}+B^{2}}}$.
is an equation representing the same locus as $A x+B y+C=0$, and having the normal form.
59. To trace the locus of an equation of the first degree. In Art. 57 it was proved that the locus of an equation of the
 first degree in two variables is a straight line; but a straight line is fully determined by any two points on it; hence, to trace the locus of a first degree equation it is only necessary to determine two of its points, and then to draw the indefinite straight line through them. The two points most easily determined, and plotted, are those in which the locus cuts the axes; they are therefore the most advantageous points to employ. If the line is parallel to an axis, then only one point is needed.
E.g., to trace the locus of the equation

$$
2 x-3 y+12=0:
$$

the ordinate of the point in which this line crosses the $x$-axis is 0 ; let its abscissa be $x_{1}$, then $\left(x_{1}, 0\right)$ must satisfy the equation $2 x-3 y+12=0$;
hence

$$
\begin{gathered}
2 x_{1}-3 \cdot 0+12=0 \\
x_{1}=-6
\end{gathered}
$$

i.e., the line crosses the $x$-axis at the point $(-6,0)$. In like manner it is shown that it crosses the $y$-axis at the point $(0,4)$. Therefore $L M$ is the locus of $2 x-3 y+12=0$.
60. Special cases of the equation of the straight line $\boldsymbol{A x}+B y+\boldsymbol{C}=\mathbf{0}$. This equation, written in the intercept form [Art. 58 (1)] becomes

$$
\begin{equation*}
\frac{x}{-\frac{C}{A}}+\frac{y}{-\frac{C}{B}}=1 \tag{1}
\end{equation*}
$$

If in equation (1), $\boldsymbol{A}$ is made smaller and smaller in comparison with $C$, then the $x$-intercept $\left(-\frac{C}{A}\right)$ becomes larger and larger ; if $A \doteq 0$ in comparison with $C$, the $x$-intercept grows infinitely large, the line (1) becomes parallel to the $x$-axis, and its equation becomes

$$
\frac{x}{\infty}+\frac{y}{-\frac{C}{B}}=1 ; \text { i.e., } y=-\frac{C}{B}
$$

which agrees with the foot-note of Art. 57.
Similarly, if $B \doteq 0$ in comparison with $C$, the line (1) becomes parallel to the $y$-axis, and its equation becomes

$$
x=-\frac{C}{A}
$$

If both $\boldsymbol{A}$ and $\boldsymbol{B}$ approach zero simultaneously in comparisom with $C$, then both the intercepts become indefinitely large, and the line (1) recedes farther and farther from the origin.

In accordance with what has just been said, a line that is wholly at infinity might have its equation written in the form

$$
\begin{equation*}
0 \cdot x+0 \cdot y+C=0 \tag{}
\end{equation*}
$$

or, as it is sometimes written, $\quad C=0$;
but equations (2) and (3) are merely abbreviations for the statement: "As both $A$ and $B$ approach zero in eomparison with $C$, the line moves farther and farther from the origin."

## EXERCISES

1. Reduce the following equations to the intercept (symmetric) form, and draw the lines which they represent:
(a) $3 x-2 y+12=0$;
(ß) $3 x-2 y+1=5 x+3$;
(y) $2 y=15-y+5 x$;
(8) $\frac{x-2 y+1}{3+5 y}=0$.
2. Reduce to the slope form, and then trace the loci:
(a) $7 x-5 y+6(y-3 x)=-10 x+4$;
( $\beta$ ) $3 x+2 y+6=0$;
(y) $3 x+5=3-y$.
Which is the positive side of the line ( $\beta$ )? (ef. foot-note, Art. 43.)
3. Reduce to the normal form, and then trace the loci:
(a) $3 x+4 y=15$;
( $\beta$ ) $3 x-4 y+15=0$;
(y) $x-3 y=5+6 x$;
(8) $\quad \frac{1}{} x=y-5$.
4. Show that the lines $3 x+5=y$ and $6 x-2 y=81$ are parallel.
5. What is the slope of the line between the two points $(3,-1)$ and $(2,2)$ ? What is its distance from the origin? Which is its negative side?
6. A line passes through the point $(5,6)$ and has its intercepts on the axes equal and both positive. Find its equation and its distance from the origin.
7. A straight line passes through the point $(1,-2)$ and is such that the portion of it between the axes is bisected by that point. What is the slope of the line?
8. What are the intercepts which the line through the points $(-1,3)$ and $(6,7)$ makes on the axes? . Through the points $(a, 2 a)$ and $(b, 2 b)$ ?
9. What system of lines obtained by varying the parameter $b$ is represented by the equation $y=6 x+b$ ?
10. What system of lines obtained by varying the parameter $m$ is represented by the equation $y=m x+6$ ?
11. What family (system) of lines obtained by varying the parameter $a$ is represented by the equation $x \cos a+y \sin a=5$ ? To what curve is each line of the family tangent?
12. Find $\cos \alpha$ and $\sin \alpha$ for the lines

$$
\begin{array}{ll}
\text { (a) } y=m x+b, & \text { (阝) } \frac{x}{a}+\frac{y}{b}=1, \\
\text { (ү) } \frac{3}{x}=\frac{2}{y}, & \text { (b) } 7 x-5 y+1=0 .
\end{array}
$$

13. Find by means of cos a and sin a what quadrant is croosed by each of the lines:
(a) $3 x+2=2 y$;
( $\beta$ ) $5 x+3 y+15=0$;
(y) $x-\sqrt{3} y-10=0$.
14. What munt be the alope of the line $t x=19=17$ in order that it shall pass through the point (1, 3)? Has $k$ a fimite value for which this lime will pess through the crigin?
15. Determine the values of $A, B, C$ in order that the line

$$
A x+B y+C=0
$$

shall pass through the pointen $(3,0)$ and $(0,12)$. [Art. 55, Note.]
16 Derive equation [9] by supposing $\left(x_{p}, y\right)$ and $\left(x_{p}, y_{2}\right)$ to be two points on the line $y=m s+h$; and thence finding values for $m$ and $b$.
17. Find the slopes of the lines $2 y-3 x=7$ and $3 y+2 x-11=0$; and thence show that these lines are perpendicular to each other.
18. Find cos a for each of the lines $\overline{7} x+y-9=0$ and $x-i y+2=0$. and then show that the two lines are juerpendicular to each other.
19. Show by means of: (1) the sloges; (2) the angles; that the lines

$$
2 y-3 x=7, \quad 2 y-3 x+5=0, \quad 10 y-15 x+c=0
$$

ave all parallel.
20. Reduce the equation $A x+B y+C=0$ to the normal form, i.e, to the form $x \cos a+y \sin a=p$. Suggeation : the two equations, as representing the same line, make the same intercepts on the axes.
61. To find the angle made by one straight line with another.

Let the equations of the lines be

$$
\begin{equation*}
y=m_{1} x+b_{1}, \ldots(1) \tag{2}
\end{equation*}
$$

and $y=m_{2} x+b_{3} \ldots$
where $m_{1}=\tan \theta_{1}, m_{2}=\tan \theta_{2}$ and $\theta_{1}, \theta_{3}$ are the angles which these lines make, respectively, with the a-axis. It is required to find the angle $\phi$, measured from line ( 2 ) to line (1).

[^19]Since

$$
\begin{gather*}
\phi=\theta_{1}-\theta_{2}, \\
\tan \phi=\frac{\tan \theta_{1}-\tan \theta_{2}}{1+\tan \theta_{1} \cdot \tan \theta_{2}},  \tag{Art.16}\\
\tan \phi=\frac{m_{1}-m_{2}}{1+m_{1} m_{2}} .
\end{gather*}
$$

If the angle were measured from line (1) to line (2) it would be the negative, or else the supplement, of $\phi$; in either case its tangent would be the negative of that given by formula [14].
If the equations of the lines had been given in the form :

$$
\begin{array}{ll} 
& A_{1} x+B_{1} y+C_{1}=0, \\
\text { and } & A_{2} x+B_{2} y+C_{2}=0, \tag{4}
\end{array}
$$

then $m_{1}=-\frac{A_{1}}{B_{1}}, m_{2}=-\frac{A_{2}}{B_{2}}$, and formula [14] becomes

$$
\begin{equation*}
\tan \phi=\frac{-\frac{A_{1}}{B_{1}}+\frac{A_{2}}{B_{2}}}{1+\frac{A_{1} A_{2}}{B_{1} B_{2}}}=\frac{A_{2} B_{1}-A_{1} B_{2}}{A_{1} A_{2}+B_{1} B_{2}} \tag{15}
\end{equation*}
$$

## EXERCISES

Find the tangent of the angle from the first line to the second in each of the following cases, and draw the figures:

1. $3 x-4 y-7=0, \quad 2 x-y-3=0$;
2. $5 x+12 y+1=0, \quad x-2 y+6=0$;
3. $2 x=3 y+9, \quad 6 y=4 x+2$;
4. $\frac{x}{a}+\frac{y}{b}=1, \quad \frac{x}{a}-\frac{y}{b}=1$;
5. $x \cos a+y \sin a=p, \quad \frac{x}{a}+\frac{y}{b}=1$.
6. Condition that two lines are parallel or perpendicular. From formula [14] can be seen at once the relations that
must hold between $m_{1}$ and $m_{2}$ if the lines (1) and ( 2 ) (Art. 61) are parallel or perpendicular. If these lines are parallel, then $\phi=0$, and therefore tan $\phi=0$;
hence

$$
\begin{gathered}
\frac{m_{1}-m_{2}}{1+m_{1} m_{3}}=0 \\
m_{1}=m_{2}
\end{gathered}
$$

which is the condition that lines (1) and (2) are parallel. This condition is also evident from a mere inspection of equations (1) and (2).

If the lines (1) and (2) (Art. 61) are perpendicular, then $\phi=90^{\circ}$ and $\tan \phi=\infty$,
i.e.,

$$
\begin{gathered}
\frac{m_{1}-m_{2}}{1+m_{1} m_{3}}=x \text {, hence } 1+m_{1} m_{2}=0, \\
m_{2}=-\frac{1}{m_{1}}
\end{gathered}
$$

which is the condition that (1) and (2) are perpendicular.
So also from [15] the lines

$$
A_{1} x+B_{1} y+C_{1}=0 \text { and } A_{2} x+B_{2} y+C_{2}=0
$$

are parallel if (and only if) $A_{2} B_{1}-A_{1} B_{2}=0$,
i.e., if $\quad A_{1}: B_{1}=A_{2}: B_{2}$;
and they are perpendicular if (and only if) $A_{1} A_{3}+B_{1} B_{2}=0$,
i.en, if

$$
A_{1}: B_{1}=-B_{2}: A_{2}
$$

The condition just found enables one to write down readily the equations of lines that are parallel or perpendicular to given lines, and which also pass through given points.

[^20]E.g., let it be required to write the equation of a line that is parallel to the line
\[

$$
\begin{equation*}
y=8 x+7 . \tag{1}
\end{equation*}
$$

\]

The slope of this line is 3 , hence any other line whose slope is 3 is parallel to the given line,
i.e.,

$$
\begin{equation*}
y=3 x+b, \tag{2}
\end{equation*}
$$

is, for all values of $b$, parallel to line (1).
If it be required that the line (2) shall also pass through a given point, $(1,5)$ for example, it is only necessary to determine rightly the value of $b$. This is done by remembering that if the line (2) passes through the point ( 1,5 ), then these coördinates must satisfy equation (2),
i.e.,

$$
5=3 \cdot 1+b \text {, whence } b=2 \text {. }
$$

Therefore the line $y=3 x+2$ is not only parallel to the line $y=3 x+7$, but also passes through the point $(1,5)$.

Similarly $y=-\frac{1}{3} x+b$, whatever the value of $b$, is perpendicular to $y=3 x+7$.

Again, the line $3 x+5 y+k=0$, whatever the value of $k$, is parallel to the line $3 x+5 y-15=0$; and the line $5 x-3 y+k=0$ is perpendicular to $3 x+5 y-15=0$. Here again the arbitrary constant $k$ may be so determined that this line shall pass through any given point. So also the lines $A_{1} x+B_{1} y+C_{1}=0$ and $A_{1} x+B_{1} y+C_{2}=0$ are parallel, while $A_{1} x+B_{1} y+C_{1}=0$ and $B_{1} x-A_{1} y+C_{2}=0$ are perpendicular to each other.

This condition for parallelism and for perpendicularity of two lines may also be stated thus: two lines are parallel if their equations differ (or may be made to differ) only in their constant terms; two lines are perpendicular if the coefficients of $x$ and $y$ in the one are equal (or can be made equal), respectively, to the coefficients of $-y$ and $x$ in the other.

## EXERCISES

1. Write down the equations of the set of lines parallel to the lises:

$$
\begin{aligned}
\text { (a) } y=6 x-2 ; & \text { (ß) } 3 x-7 y=3 ; \\
\text { (y) } x \cos 30^{\circ}+y \sin 30^{\circ}=8 ; & \text { (ठ) } \frac{x}{2}-\frac{y}{3}=1 .
\end{aligned}
$$

2. Explain why it is that the constant term in the answers to Ex. 1 is left undetermined or arbitrary.
3. Find the tangent of the angle lnetween the lines $(a)$ and $(\beta)$ ins E.x. 1 ; also for the lines $(\beta)$ and $(\delta)$, and $(a)$ and $(\delta)$ of Ex. I.
4. Write the equations of lines peipendicular to ctoose given in Ex. 1.
 through the point $(3,1)$, and is parallel to the line $y=6 z-2$.
5. Solve Ex, 4 by means of equation [11], Art. 53.
6. Find the equation of the line that is parallel to the line $A x+B y$ $+C=0$ and that prases through the point $\left(x_{1}, y_{1}\right)$; uake two solutions, one by the methoul of Ex. 8, and the other by Eix. 5.

Find the equation of the straight line
8. through the point $(2,-5)$ and parallel to the line $y=2 x+7$.
9. through the point $(-1,-1)$ and perpendicular to $y=2 z+7$; solve by two methods.
10. through the point $(0,0)$ and parallel to the line

$$
\frac{3}{2} x-\frac{7}{5} y=\frac{x-y+1}{9}
$$

11. perpendicular to the line $2 y+7 x-1=0$, and passing through the point midway between the two points in which this lue meets the cocirdisuate axes.
12. Find the foot of the perpendicular from the origin to the line $3 x-7 y=2$.

## 63. Line which makes a given angle with a given line.

 The formula$$
\tan \phi=\frac{\tan \theta_{1}-\tan \theta_{3}}{1+\tan \theta_{1} \tan \theta_{2}}(\text { Art. 61) }
$$

states the relation existing between the tangents of the angles $\theta_{1}, \theta_{2}$, and $\phi$ (see Fig. 47), hence if any two of these
angles are known, this equation determines the value of the third. Thus this formula may be employed to determine the slope of a line that shall make a given angle with a given line.
E.g., given the line $3 y-5 x+7=0$, to find the equation of a line that shall make an angle of $60^{\circ}$ with this line. Here $\phi=60^{\circ}$, i.e., $\tan \phi=\sqrt{3}$, and if $\theta_{1}$ be the angle which the given line makes with the $x$-axis, and $\theta_{2}$ that made by the line whose equation is sought, then $\tan \theta_{1}=\frac{5}{3}$. Substituting these values in the above formula, it becomes

$$
\sqrt{3}=\frac{\tan \theta_{2}-5}{1+\frac{5}{3} \tan \theta_{2}},
$$

whence

$$
\tan \theta_{2}=\frac{5+3 \sqrt{3}}{3-5 \sqrt{3}}, \text { and } y=\frac{5+3 \sqrt{3}}{3-5 \sqrt{3}} \cdot x+k
$$

is the equation of a line fulfilling the required conditions, $k$ may be so determined that this line shall also pass through any given point.

It is to be remarked that through any given point there may be drawn two lines, each of which shall make, with a given line, an angle of any desired magnitude.

E.g., through $P_{1} \equiv\left(x_{1}, y_{1}\right)$ the lines (1) and (2) may be so drawn that each shall make an angle $\phi$ with the given
line LM. Let line (1) make an angle $\theta_{1}$. line (2) an angle $\theta_{2}$ and $L M$ an angle $\theta_{8}$, with the $\varepsilon$-axis ; then

$$
\phi=\theta_{1}-\theta_{3} \text {, and } 180-\phi=\theta_{2}-\theta_{3} \text {. }
$$

which gives

$$
\tan \phi=\frac{\tan \theta_{1}-\tan \theta_{3}}{1+\tan \theta_{1} \tan \theta_{3}} \text {, and }-\tan \phi=\frac{\tan \theta_{2}-\tan \theta_{3}}{1+\tan \theta_{3} \tan \theta_{3}}
$$

In these equations $\phi$ and $\theta_{3}$ are knswn, hence tan $\theta_{1}$ and $\tan \theta_{3}$ can be found. Having found $\tan \theta_{1}$ and $\tan \theta_{2}$ the equations of lines (1) and (2) may at once be written down, either by means of equation [ $1 \mathrm{i} j$, of oy the method employed in Art. 62.

## EXERCISES

1. Find the equations of the two lines which pass through the point (5.8), and each of which makes an angle of $45^{\circ}$ with the line $2 x-3 y=6$.
2. Show that the equations of the two straight lines pasaing through the point $(3,-2)$ and inclined at $60^{\circ}$ to the line $x \sqrt{3}+y=1$ are

$$
y+2=0 \text { and } y-x \sqrt{3}+2+3 \sqrt{3}=0 .
$$

Find the equation of the straight line
3. making an angle of $+\frac{\pi}{4}$ with the line $3 x-4 y=7$; construct the figure. Why is there an undetermined constant in the resulting equation?
4. making an angle of $-60^{\circ}$ with the line $5 x+12 y+1=0$; construes the figure.
5. making an angle of $+30^{\circ}$ with the line $x-2 y+1=0$, and passing through the point ( 1,3 ); making an angle of $-30^{\circ}$, and passing through the same point.
6. making an angle of $\pm 185^{\circ}$ with the line $x+y=2$, and passing through the origin.
7. making the angle $\tan ^{-1}\left(-\frac{b}{a}\right)$ with the line $\frac{x}{a}+\frac{y}{b}=1$, and passing through the point $\left(\frac{a}{2} \frac{b}{2}\right)$.
8. Find the equation of a line thmugh the paint $(t, 5)$ forming with the lines $2 x-y+3=0$ and $3 y+6 x=7$ a rightangled triangle. Find the vertices of the triangle (two solutions).
9. Show that the triangle whose vertices are the points $(2,1),(3,-2)$, $(-4,-1)$ is a right triangle.
10. Prove analytically that the perpendiculars erected at the middle points of the sides of the triangle, the equations of whose sides are

$$
x+y+1=0,3 x+5 y+11=0, \text { and } x+2 y+4=0
$$

meet in a point which is equidistant from the vertices.
11. Find the equations of the lines through the vertices and perpendicular to the opposite sides of the triangle in exercise 10. Prove that these lines also meet in a common point.
12. A line passes through the point $(2,-3)$ and is parallel to the line through the two points $(4,7)$ and $(-1,-9)$; find its equation.
13. Find the equation of the line which passes through the point of intersection of the two lines $10 x+5 y+11=0$, and $x+2 y+14=0$, and which is perpendicular to the line $x+7 y+1=0$.

This problem may be solved by first finding the point of intersection ( $46,-\frac{43}{5}$ ) of the two given lines, and then, by formula [11] (see also Art. 62), writing the equation of the required line, viz.:

$$
\begin{gathered}
y+\frac{y 3}{3}=7\left(x-\frac{16}{\delta}\right) \\
7 x-y=31
\end{gathered}
$$

which reduces to
The problem may also be solved somewhat more briefly, and much more elegantly, by employing the theorem of Art. 41. By this theorem the equation of the required line is of the form

$$
\begin{array}{r}
10 x+5 y+11+k(x+2 y+14)=0 \\
\text { i.e., } \quad(10+k) x+(5+2 k) y+11+14 k=0
\end{array}
$$

It only remains to determine the constant $k$, so that this line shall be perpendicular to $x+7 y+1=0$. By Art. 62 its slope must be $-\frac{1}{-1}=7$, hence $-\frac{10+k}{5+2 k}=7$, whence $k=-3$.

Substituting this value of $k$ above, the required equation becomes $7 x-y=31$, as before.
14. By the second method of exercise 13 find the equation of the line which passes through the print of intersection of the two lines $2 x+y=5$ and $x=3 y-8$, and which is: (1) parallel to the line $4 y={ }^{R} x+1$; (2) perpendicular to this line; (3) inclined at an angle of $60^{\circ}$ to this lint ; (4) passes through the point ( $-1,3$ ).
15. Solve exercise 10 by the method of exercise 14
16. Do the linms $2 x+3 y=13,5 x-y=7$. and $z-4 y+10=0$ mese in a common protst? What are the angles thery make with each other?
17. Find the angles of the triangle of excercine 10.
16. When are the lines

$$
z+(a+b) y+c a 0 \text { and } a(x+a y)+b(x \cdots b y)+d=0
$$

parallel? when perpendicular?
19. Find the value of $p$ for each of the two purallel lines

$$
y=8 x+7 \text { and } y=3 x-5
$$

and hence find the distance between these lines [ Cf . Art. 58 ( 3 ) and ( 1 )].
20. What in the distance between the two prarallel linea

$$
5 x-3 y+6=0 \text { and } 6 y-10 x=7 \text { ? }
$$

21. Find the cosine of the angle between the lines

$$
y-4 x+8=0 \text { and } y-6 x+9=0
$$

22. What relation exists between the two lines

$$
y=3 x+7 \text { and } y=-8 x-3 ?
$$

23. Find the angle between the two straight lines $3 x=4 y+7$ and $5 y=12 x+6$ : and also the equations of the two straight lines which pras through the point $(4,5)$ and make equal angles with the two given lines.
24. Find the augle between the two lines

$$
8 x+y+12=0 \text { and } x+2 y-1=0
$$

Find also the coordinates of their point of intersection, and the equations of the lines drawn perpendicular to them from the point $(3,-2)$.
64. The distance of a given point from a given line. This problem is easily solved for any particular case thus: find the equation of the line which passes through the given point and which is parallel to the given line (Art. 62), then find the distance $(p)$ from the origin to each of these two lines [Art. 58, (3) and (4)], and finally subtract one of these distances from the other ; the result is the distance between the given line and the given point.
E.g., find the distance of the point $P_{1} \equiv\left(2, \frac{3}{2}\right)$ from the line

$$
\begin{equation*}
3 x+4 y-7=0 \tag{1}
\end{equation*}
$$

Let line (1) be the locus of equation (1), and $P_{1}$ be the given point. Through $P_{1}$ draw the line (2) parallel to line (1), also draw Q $P_{1}$ perpendicular to line (1), $O R_{1}\left(=p_{1}\right)$ perpendicular to line (1), and $O R_{2}\left(=p_{2}\right)$ perpendicular to line (2). Then $d=Q P_{1}=p_{2}-p_{1}$.

The equation of a line parallel to line (1) is of the form $3 x+4 y+k=0$; this will represent line (2) itself if $k$ he so determined that the line shall pass through the point

$$
P_{1} \equiv\left(2, \frac{3}{2}\right), \text { i.e., if } 3 \cdot 2+4 \cdot \frac{3}{2}+k=0, \text { i.e., if } k=-12 .
$$

The equation of line (2) is then

$$
\begin{equation*}
3 x+4 y-12=0 \tag{2}
\end{equation*}
$$

Therefore [by Art. 58, (3) or (4)]

$$
p_{:}=\frac{12}{+\sqrt{4^{2}+3^{2}}}=\frac{12}{5}, \text { and } p_{1}=\frac{7}{+\sqrt{t^{2}+3^{2}}}=\frac{7}{5}
$$

hence the requ red distance is $d={ }^{\circ} Q P_{1}=\frac{12-7}{5}=1$.
Similarly, in general, to find the distance of any given point $P_{1} \equiv\left(x_{1}, y_{1}\right)$ from any given line

$$
\begin{equation*}
A x+B y+C=0 \tag{1}
\end{equation*}
$$

let line (1) be the locus of equation (1) and let $P_{1}$ be the given point. The equation of a line parallel to (1) is of the form $A x+B y+K=0$, this will be the line (2) if
$A x_{1}+B y_{1}+K=0$, i.e., if $K=-\left(A x_{1}+B y_{1}\right)$. The equation of lime (2) is then

$$
\begin{equation*}
A x+B y-\left(A x_{1}+B y_{1}\right)=0 . \tag{2}
\end{equation*}
$$

Therefore $\quad p_{2}=\frac{A x_{1}+B y_{1}}{\sqrt{A^{2}+B^{2}}}, \quad p_{1}=\frac{-D}{\sqrt{A^{2}+B^{2}}}$.
wherein the sign of the radical is to be chosen opposite to that of the number represented by $\bar{C}$,
hence

$$
\begin{equation*}
a=\frac{A x_{1}+B y_{1}+C}{\sqrt{A^{2}+B^{2}}} . \tag{16}
\end{equation*}
$$

If the equation of the given line is so written that its second member is zero, this formula may be translated into words thus: To get the distance of a given point from a given line, write the first member of the equation alone, substitute fur the variables therein the coordinates of the gieen point, and dieide the resull by the square root of the sum of the squares of the coefficients of $x$ and $y$ in the equation, - the sign of this square root being chosen opposite to that of the number represented by $C$.

If, in formula [16], $d$ is positive, then $p_{3}>p_{1}$, and $P_{1}$ and the origin are on opposite sides of the given line; if $d$ is negative, $p_{2}<p_{1}$, and $P_{1}$ and the origin are on the same side of the given line.

## EXERCISES

1. Find the distance of the point $(2,-i)$ from the line $3 x-6 y+1=0$.

By formula [16], $d=\frac{3 \cdot 2-6(-\overline{7})+1}{-\sqrt{3^{2}+6^{3}}}=-\frac{49}{3 \sqrt{5}}$
This result, besides giving the numerical value of the distances shows also that the point $\left(2,-\frac{1}{1}\right)$ and the origin are on the same side of the line $3 x-6 y+1=0$.
2. Find the distance of the point ( 4.5 ) from the line $4 y+5 x=20$.
3. Find the distance of the point $(2,7)$ from the line $3 y-2 x=1$.
4. Find the distance of the point $(a, b)$ from the line $\frac{x}{a}+\frac{y}{b}=1$.
5. Find the distance of the intersection of the two lines, $y+4=3 x$ and $5 x=y-2$, from the line $2 y-7=9$. On which side of the latter line is the point?
6. Find the distance of the point of intersection of the lines $2 x-5 y=11$ and $4 x=3 y+15$ from the line $\frac{1}{2} x+\frac{y-5}{4}=6$. On which side of the latter line is the point? Plot the figure.
7. How far is the point $(-6,-1)$ from $3 y=7 x+8$ ? On which side?
8. By the method of Art. 64, find the distance of the origin from the line $5 x-2 y=7$; also from the line $A x+B y+C=0$. Check the results by Art. 58 (3).
9. Find the distance of the point $(-4,-5)$ from the line joining the two points $(3,-1)$ and $(-4,2)$. On which side is it ?
10. Find the distance of the point $\left(x_{1}, y_{1}\right)$ from the line $y=m x+b$.
11. Find the altitudes of the triangle formed by the lines whose equations are $x+y+1=0,3 x+5 y+11=0$, and $x+2 y+4=0$. Check the result by finding the area of the triangle in two ways.
12. Show analytically that the locus of a point which mores so that the sum of its distances from two given straight lines is constant is itself a straight liue.
13. Express by an equation that the point $P_{1} \equiv\left(x_{1}, y_{1}\right)$ is equally distant from the two lines $2 x-y=11$ and $4 x=3 y+5$. (Give two answers.) Should $P_{1}$ move in such a way as to be always equidistant from these two lines, what would be the equation of its locus?
14. Find, by the method of exercise 13 , the equations of the bisectors of the angle formed by the lines $3 x+4 y=12$ and $4 x+3 y=24$.
65. Bisectors of the angles between two given lines. The bisector of an angle is the locus of a point which moves so that it is always equally distant (numerically) from the sides of the angle. From this property its equation may easily be found.
E.I., find the equations of the bisectors of the angles between the lines
and

$$
\begin{array}{r}
3 x+4 y-1=0 \\
12 x-5 y+6=0 \tag{2}
\end{array}
$$

Let $P_{1} \equiv\left(x_{1}, y_{1}\right)$ be any point on the bisector (3).

Then $Q_{1} P_{1}=-R_{1} P_{1}$ [since $O$ and $P_{1}$ are on oprosite sides of line (1) and on the same side of (2); or vice versa].

But $\bar{Q}_{1} P_{1}=\frac{3 x_{1}+4 y_{1}-1}{+\sqrt{3^{2}+4^{2}}}$

$$
=\frac{8 x_{1}+4 y_{3}-1}{5},(\text { Art. 64) }
$$

Fo. 50.
and

$$
\begin{array}{r}
R_{1} P_{1}=\frac{12 x_{1}-5 y_{1}+1 i}{-\sqrt{12^{2}+5^{2}}}=\frac{12 x_{1}-5 y_{1}+6}{-18} ; \\
\quad \therefore \frac{3 x_{1}+4 y_{1}-1}{5}=\frac{12 x_{1}-5 y_{1}+6}{18} ;
\end{array}
$$

$$
\begin{equation*}
\text { i.e., } 21 x_{1}-77 y_{1}+43=0 . \tag{5}
\end{equation*}
$$

Hence

$$
\begin{equation*}
21 x-77 y+43=0 \tag{6}
\end{equation*}
$$

is the equation of the bisector (3), for equation (5) asserts that if $\left(x_{1}, y_{1}\right)$ be the coürdinates of any point on this bisector they satisfy equation (6).

Similarly, let $\boldsymbol{P}_{3} \equiv(h, k)$ be any point on line (4), the other bisector, then $Q_{2} P_{2}=R_{2} P_{2}$ [since $O$ and $P_{2}$ are on opposite sides of the lines (1) and (2), or else both on the same side of each of these lines];

$$
\frac{3 h+4 k-1}{5}=-\frac{12 h-5 k+6}{13}
$$

i.e.,

$$
\begin{align*}
& 99 k+27 k+17=0 . .  \tag{i}\\
& 99 x+27 y+17=0 . \tag{8}
\end{align*}
$$

Hence
is the equation of the bisector (4), for the same reason as given above.

Geometrically it is well known that two such bisectors, (3) and (4), are perpendicular to each other: their equations also prove that fact.

The equations of the bisectors of the angles between any two lines, as $A_{1} x+B_{1} y+C_{1}=0$ and $A_{2} x+B_{2} y+C_{2}=0$, are found in precisely the same way as that employed in the numerical example just considered.

## EXERCISES

1. Find the equations of the bisectors of the angles between the two lines $x-y+6=0$ and $\frac{3 x-4}{2}=5 y-7$.
2. Show that the line $11 x+3 y+1=0$ bisects one of the angles between the two lines $12 x-5 y+7=0$, and $3 x+4 y-2=0$. Which angle is it? Find the equation of the bisector of the other angle.
3. Show analytically that the bisectors of the interior angles of the triangle whose vertices are the points $(1,2),(5,3)$, and $(4,7)$ meet in a sommon point.
4. Show analytically, for the triangle of Ex. 3, that the bisectors of one interior and the two opposite exterior angles meet in a common point.
5. Find the angle from the line $3 x+y+12=0$ to the line $a x+b y$ $+1=0$, and also the angle from the line $a x+b y+1=0$ to the line $x+2 y-1=0$.

By imposing upon $a$ and $b$ the two conditions: (1) that the angles just found are equal, and (2) that the line $a x+b y+1=0$ passes through the intersection of the other two lines, determine $a$ and $b$ so that this line shall be a bisector of one of the angles made by the other two given lines.
66. The equation of two lines. By the reasoning given in Art. 40, it is shown that if two straight lines are represented by the equations
and

$$
\begin{align*}
& A_{1} x+B_{1} y+C_{1}=0  \tag{1}\\
& A_{2} x+B_{2} y+C_{2}=0
\end{align*}
$$

then both these lines are represented by the equation

$$
\begin{equation*}
\left(A_{1} x+B_{1} y+C_{1}\right)\left(A_{2} x+B_{2} y+C_{2}\right)=0 \tag{3}
\end{equation*}
$$

i.e., two straight lines are here represented by an equations of the accond degree.

Conversely, if an equation of the second degree, whose second member is zero, can have its first member separated into two first degree factors, with real cofflicients, as in equation (3). then its locus consists of two straight lines

Thus the equation

$$
2 x^{2}-x y-3 y^{2}+9 x+1 y+7=0
$$

may be written in the form

$$
(2 x-3 y+i)(x+y+1)=0
$$

which shows that it is satisfied when $2 x-3 y+7=0$, and also when $x+y+1=0$. Its locus is therefore composed of the two lines whose equations are :

$$
2 x-3 y+7=0, \text { and } x+y+1=0
$$

67. Condition that the general quadratic expression may be factored. The most general equation of the second degree between two variables may be written in the form

$$
\begin{equation*}
A x^{2}+2 \Pi x y+B y^{2}+2 G x+2 F y+C=0 \ldots \tag{1}
\end{equation*}
$$

It is required to find the relation that must exist among the confficients of this equation in order that its first member may be separited into two rational factors, each of the first degree, i.e., it is required to find the condition that the equation may be written thus:

$$
\begin{equation*}
\left(a_{1} x+b_{1} y+c_{1}\right)\left(a_{2} x+b_{2} y+c_{2}\right)=0 . \tag{2}
\end{equation*}
$$

Evidently if equation (1) can be written in the form of equation (2), then the values of $x$ obtained from equation (1) are rational, and are either

$$
x=\frac{-c_{1}-b_{1} y}{a_{1}} \text { or } x=\frac{-c_{2}-b_{2} y}{a_{2}} .
$$

Solving equation (1) for $x$ in terms of $y$, by completing the square of the $x$-terms, it beeomes

$$
\begin{gathered}
A^{2} x^{2}+2 A(H y+G) x+(H y+G)^{2} \\
=-A B y^{2}-2 A F y-A C+(H y+G)^{2}, \\
A x+H y+G \\
\text { i.e., } \quad \\
=\sqrt{\left(H^{2}-A B\right) y^{2}+2(H G-A F) y+G^{2}-A C},
\end{gathered}
$$

and finally,
$x=-\frac{H}{A} y-\frac{G}{A} \pm \frac{1}{A} \sqrt{\left(H^{2}-A B\right) y^{2}+2(H G-A F) y+G^{2}-A C}$.
But since $x$ is, by hypothesis, expressible rationally in terms of $y$, therefore the expression under the radical sign is a perfect square, and therefore

$$
\begin{align*}
& (H G-A F)^{2}-\left(H^{2}-A B\right)\left(G^{2}-A C\right)=0 \\
& \text { i.e., } \quad \boldsymbol{A B C}+2 \boldsymbol{F} \boldsymbol{G} \boldsymbol{H}-\boldsymbol{A} \boldsymbol{F}^{2}-\boldsymbol{B} \boldsymbol{G}^{2}-\boldsymbol{C} \boldsymbol{H}^{2}=0 . \tag{17}
\end{align*}
$$

If this condition among the coëfficients is fulfilled, then equation (1) has for its locus two straight lines.

The expression $A B C+2 F G H-A F^{2}-B G^{2}-C H^{2}$ is called the discriminant of the quadratic, and is usually represented by the symbol $\Delta$.

Note. The analytic work just given fails if $A=0$. In that case equation (1) may be solved for $y$ instead of solving it for $x$, and the same condition, viz. $\Delta=0$, results. If, however, both $A$ and $B$ are zero, then the above method fails altogether. In that case equation (1) reduces to

$$
\begin{equation*}
2 H x y+2 G x+2 F y+C=0 . \tag{3}
\end{equation*}
$$

If the first member of equation (3) can be factored, then evidently the equation must take the form

$$
\begin{equation*}
(a x+b)(c y+d)=0 \tag{4}
\end{equation*}
$$

which shows that equation (3) is satisfied for all finite values of $y$ provided $z=-\frac{b}{a}$, a constant. Let $-\frac{b}{a}$ be represented by $k$, then equation (4)
becomes
i.e., $\quad 2(H k+F) y+2 G k+C=0$,
and is satisfied for all finite values of $y$;

$$
\therefore \quad H k+F=0, \text { and } 2 G k+C=0 ;
$$

hence, eliminating $k$,

$$
2 F G-C H=0 .
$$

But this is the expression to which $\Delta$ reduces when $A=B=0$ and If $A 0$; hence, in all cases, $\Delta=0$ is the necessury comdition that the shove quadratio may be factored.

That $\Delta=0$ is also the suffecien condition is readily seen by retracing the steps from equation [17] when at least one of the covefficients $A$, is differs from zero. But it is alsos suffieient when $A=B=0$; for, in that case, $\Delta=0$ becomes $2 F G-C H=0$, which may be written $\frac{F}{H} \frac{G}{11}=\frac{C}{2 I I}$ I'mider the same civeranstances equation (1) becomes equation (3), which may be written

$$
\begin{equation*}
x y+\frac{G}{H} x+\frac{F}{H} y+\frac{C}{2 H}=0 . \tag{4}
\end{equation*}
$$

Substituting $\frac{F}{H} \cdot \frac{G}{H}$ for $\frac{C}{2 H}$ in equation (4), it becomes

$$
\begin{equation*}
x y+\frac{G}{H} x+\frac{F}{H} y+\frac{G}{H} \cdot \frac{F}{H}=0 \ldots \tag{5}
\end{equation*}
$$

i.e,

$$
\left(x+\frac{F}{H}\right)\left(y+\frac{G}{H}\right)=0,
$$

which establishes the sufficiency of the condition for this case also.
To illustrate the use of equation [17]* examine the equation of Art. 610 :

$$
2 x^{2}-x y-3 y^{2}+9 x+4 y+7=0 .
$$

- As an illustration of another practical method of factoring a quadratic expression, wehen fuctoring is possible. i.e., if equation [17] bolds, find the fictors of

$$
2 x^{3}-7 k y-15 y^{4}+7 x+17 y-4 .
$$

This locus cuts the $x$-axis at the points $(1,0),(-4,0)$ and the $y$-axis at (0. f), (0, 8$)$; hence the two lines are cither

$$
\frac{x}{1}+\frac{y}{1}=1 \text { and } \frac{x}{-4}+\frac{y}{y}=1 \text {, or } \frac{x}{1}+\frac{y}{1}=1 \text { and } \frac{x}{-4}+\frac{y}{3}=1 \text {; }
$$

therefore the factors are either

$$
2 x+3 y-1 \text { and } x-6 y+4 \text {, or } 8 x+6 y-4 \text { and } x-12 y+4 \text {. }
$$

Inspection shows that they are $(2 x+3 y-1)$ and $(z-6 y+4)$.

Here

$$
A=2, B=-3, C=7, H=-\frac{1}{2}, \quad\left(i=\frac{9}{2}, \text { and } F=2 ;\right.
$$

hence

$$
\Delta=-42-9-8+\frac{243}{4}-\frac{7}{4}=0
$$

therefore the first member can be factored.
The factors may be found as follows: transposing, dividing by 2 , and completing the square of the $x$-terms, the equation may be written in
the form

$$
\begin{gathered}
x^{2}+\frac{9-y}{2} x+\left(\frac{9-y}{4}\right)^{2}=\frac{25}{16}\left(y^{2}-2 y+1\right) \\
\left(x+\frac{9-y}{4}\right)^{2}=\left\{\frac{5}{4}(y-1)\right\}^{3}
\end{gathered}
$$

therefore the given equation, divided by 2, may be written in the form,

$$
\left(x+\frac{9-y}{4}\right)^{2}-\left\{\frac{5}{4}(y-1)\right\}^{2}=0 ;
$$

i.e., $\quad\left\{\left(x+\frac{9-y}{4}\right)+\frac{5}{4}(y-1)\right\}:\left\{\left(x+\frac{9-y}{4}\right)-\frac{5}{4}(y-1)\right\}=0$,
i.e., $\quad(x+y+1)\left(x-\frac{1}{2} y+\frac{7}{2}\right)=0$;
hence the locus of the original equation consists of the straight lines

$$
x+y+1=0 \text { and } 2 x-3 y+7=0
$$

which agrees with the result of Art. 66.

## EXERCISES

Prove that the following equations represent pairs of straight lines ; find in each case the cquations of the two lines, the coördinates of their point of intersection. and the angle between them.

1. $6 y^{2}-x y-x^{2}+30 y+36=0$.
2. $x^{2}-2 x y-3 y^{2}+2 x-2 y+1=0$.
3. $x^{2}-2 x y \sec \alpha+y^{2}=0$.
4. $x^{2}+6 x y+9 y^{2}+4 x+12 y-5=0$.
5. For what value of $k$ will the equation

$$
x^{2}-3 x y+y^{2}+10 x-10 y+k=0
$$

represent two straight lines?
Suggestion: Place the discriminant $(\Delta)$ equal to zero, and thus find $k=20$.

Find the values of $k$ for which the following equations represent pairs of straight lines. Find also the equation of each line, the point of intersection of each pair of lines, and the angle between them.
6. $6 x^{2}+2 k x y+12 y^{2}+22 x+31 y+20=0$.
7. $12 x^{2}+36 x y+k y^{2}+6 x+6 y+3=0$.
8. $4 x^{3}-12 x+9 y^{2}-2 x+8 y+1=0$.
9. The equations of the opporite sitles of a parallelograms are

$$
x^{2}-7 x+8=0 \text { and } y^{2}-14 y+40=0 .
$$

Find the equations of the diagonals.
10. Find the conditions that the atraight lines represented by the equar tion $A x^{2}+2 B x y+C y^{3}=0$ may be real; imaginary; coincident; perpetsdicular to each other.
11. Show that $6 x^{2}+5 x y-6 y^{2}=0$ is the equation of the bisectors of the angles made by the lines $2 x^{2}+12 x y+7 y^{8}=0$. Does the first set of lines fulfil the test of exercise 10 for perpendicularity?
68. Equations of straight lines: coordinate axes oblique. Sinee in the derivation of equations [9] and [10] (Arts. 51 and 52 ) only properties of similar triangles were employed, therefore these two equations are true whether the coordinate axes are rectangular or oblique.

The other three standard forms however, viz. $y=m x+b$, $y-y_{1}=m\left(x-x_{1}\right)$, and $x \cos a+y \sin a=p$, the derivation of which depends upon right triangles, are no longer true if the axes are inclined to each other at an angle $\omega \neq \frac{\pi}{2}$. Equations which correspond to these, but which are referred to oblique axes, will now be derived.
(1) Equation of straight line through a given point and in a given direction. Let $L L_{1}$ be the straight line through the fixed point $P_{1} \equiv\left(x_{1}, y_{1}\right)$ and making an angle $\theta$ with the $x$-axis, let $P \equiv(x, y)$ be any other point on $L L_{1}$, and let $\infty$ be the angle between the axes.

Draw $P_{1} R$ parallel to the
 $x$-axis, also draw the ordinates $M_{1} P_{1}$ and $M P$. Then

$$
\theta=\angle X A L=\angle R P_{1} L \text { and } \angle P_{1} P R=0-\theta .
$$

Hence $\quad \frac{R P}{P_{1} R}=\frac{\sin \theta}{\sin (\omega-\theta)}$. [law of sines]
Substituting in this equation the coördinates of $P_{1}$ and $P$, it becomes
i.e.,

$$
\begin{gather*}
\frac{y-y_{1}}{x-x_{1}}=\frac{\sin \theta}{\sin (\omega-\theta)} \\
y-y_{1}=\frac{\sin \theta}{\sin (\omega-\theta)}\left(x-x_{1}\right), \tag{18}
\end{gather*}
$$

which is the required equation.
When $\omega=\frac{\pi}{2}$ this equation reduces to equation [11], i.e., to $y-y_{1}=m\left(x-x_{1}\right)$, where $m=\tan \theta$; but it must be observed that if $\omega \neq \frac{\pi}{2}$, then the coefficient of $x$ in equation [18] does not represent the slope of the line. If, however, the slope of the line [18], i.e., the $\tan \theta$ for this line, is desired, it is easily found thus : let $\frac{\sin \theta}{\sin (\omega-\theta)}=k$, from which is obtained $\tan \theta=\frac{k \sin \omega}{1+k \cos \omega}$.

If, in the derivation of equation [18], the given point is that in which the line $L L_{1}$ meets the $y$-axis, i.e., if $P_{1} \equiv(0, b)$, then equation [18] reduces to

$$
y=\frac{\sin A}{\sin (\omega-\theta)} x+b, \quad . \quad . \quad . \quad[19]
$$

which corresponds to equation [12], but the coefficient of $x$ is not the slope of the line.
(2) Equation of a straight line in terms of the perpendicular upon it from the origin, and the angles which this perpendicular makes with the axes.

Let $L L_{1}$ be the straight line whome equation is sought, lee the perpendicular from the origin upon it ( $O N=p$ ) make the angles $a$ and $\beta$ respectively with the axes, and let $P=$ $(x, y)$ be any point on $L L_{1}$.

Draw the ordinate MP ; then,
 by Art. 17,

$$
\begin{gather*}
O M \cos a+M P \cos \beta=O N \\
x \cos a+y \cos \beta=p \tag{20}
\end{gather*}
$$

i.e.,
which is the required equation.
If $\omega$ is the angle between the axes, then $\beta=\omega-a$, and equation [20] may be written $x \cos a+y \cos (\omega-a)=p$. If $\omega=\frac{\pi}{2}$, then this equation reduces to $x \cos a+y \sin a=p$, which agrees with equation [13].

## EXERCISES

1. The axes being inclined at the angle $60^{\circ}$, find the inclination of the line $y=2 x+5$ to the $x$-axis.
2. The axes being inclined at the angle $\frac{\pi}{4}$, find the angles at which the lines $3 y+7 x-1=0$ and $x+y+2=0$ cross the $x$-axis.
3. Find the anglo between the lines in exercime 2.
4. The center of an equilateral triangle of side 6 is joined by straight limes to the vertices. If two of these lines are taken as coordinate axes, find the coordinates of the vertices, and the equations of the sides.
5. Prove that for every value of $a$, the lines $x+y=c$ and $x-y=d$ are perpendicular to each other.

[^21]69. Equations of straight lines: polar coördinates.
(1) Line through two given points. Let $O R$ be the initial line, $O$ the pole, $P_{1}$
 $\equiv\left(\rho_{1}, \theta_{1}\right)$, and $P_{2} \equiv$ ( $\rho_{2}, \theta_{2}$ ), the two given points, and let $P \equiv$ $(\rho, \theta)$ be any other point on the line through $P_{1}$ and $P_{2}$.
Then (if $\Delta$ stands for 'area of triangle')
$$
\triangle O P_{1} P_{2}=\triangle O P_{1} P+\triangle O P P_{2}
$$
i.e., $\frac{1}{2} \rho_{1} \rho_{2} \sin \left(\theta_{2}-\theta_{1}\right)=\frac{1}{2} \rho \rho_{1} \sin \left(\theta-\theta_{1}\right)+\frac{1}{2} \rho_{2} \rho \sin \left(\theta_{2}-\theta\right)$,
hence $\quad \rho \rho_{1} \sin \left(\theta-\theta_{1}\right)+\rho_{1} \rho_{2} \sin \left(\theta_{1}-\theta_{2}\right)$
$$
+\rho_{2} \rho \sin \left(\theta_{2}-\theta\right)=0 . * \cdot[21]
$$

This equation may also be written in the form

$$
\frac{\sin \left(\theta_{1}-\theta_{2}\right)}{\rho}+\frac{\sin \left(\theta_{2}-\theta\right)}{\rho_{1}}+\frac{\sin \left(\theta-\theta_{1}\right)}{\rho_{2}}=0 . *
$$

(2) Equation of the line in terms of the perpendicular upon it from the pole, and the angle which this perpendicular makes with the initial line. Let $O R$ be the initial line, $O$ the pole, and $L K$ the line whose equation is sought. Also, let $N \equiv(p, a)$ be the foot of the perpendicular from $O$ upon $L K$, and let $P \equiv(\rho, \theta)$ be any other point on $L K$. Draw $O N$ and $O P$; then

$$
\begin{array}{ll} 
& \frac{O N}{O P}=\cos N O P \\
\text { i.e., } \quad & \rho \cos (\theta-a)=p
\end{array}
$$

which is the required equation.

[^22]
## EXERCISES

1. Construct the lines:
(a) $p \cos (\theta-3 \Gamma)=10$;
(c) $\rho \cos \left(\theta-\frac{\pi}{i}\right)=9$;
(b) $p \sin \theta=2$;
(d) $\rho \mathrm{cen}(\bar{\theta}=\bar{\pi})=\mathrm{C}$.
2. Find the polar equations of straight lines at a distance 3 from the pale, and : (1) parallel to the initial line; (2) perpendiculars to the initial line.
3. A straight line pamen through the points $\left(5,-45^{\circ}\right)$ and $\left(3,00^{\circ}\right)$; find its polar equation.
4. Find the polar equation of a line passing through a given point $\left(\rho_{0}, \theta_{1}\right)$ and cutting the initial line at a given angle $\phi=\tan ^{-1} \mathrm{t}$.
5. Find the pular coordinates of the point of intersection of the lines

$$
\rho \cos \left(\theta-\frac{\pi}{2}\right)=2 a, \quad \rho \cos \left(\theta-\frac{\pi}{6}\right)=a .
$$

## EXAMPLES ON CHAPTER V

1. The points $(-1,2)$ and $(3,-2)$ are the extremities of the base of an equilateral triangle. Find the equations of the sides, and the courdinates of the third vertex. Two solutions.
2. Three of the vertices of a parallelogram are at the pmints $(1,1)$. (3,4), and (5, 2). Find the fourth vertex. (Three solutions.) Fiond also the area of the parallelogram.
3. Find the equations of the two lines drawn through the point ( 0,3 ), such that the perpendiculars let fall from the point ( 6,6 ) upon them are each of leugth 3 .
4. Perpendiculars are let fall from the point $(5,0)$ upon the sides of the triangle whose vertices are at the points $(4,3),(-4,3)$, and $(0,-5)$. Show that the feet of these three perpendiculars lie on a straight line.

Find the equation of the straight line
5. through the origin and the point of intersection of the lines $x-y=4$ and $7 x+y+20=0$. Prove that it is a bisector of the angle formed by the two given lines.
6. through the intersectioa of the lines $3 x-4 y+1=0$ and $5 x+y=1$, and cutting off equal intercepts from the axes.
7. through the point ( 1,2 ), and intersecting the line $x+y=4$ at a distance $\$ \sqrt{6}$ from this point.
8. A line drawn through the point $(4,5)$ makes an isosceles triangle with the lines $3 x=4 y+7$ and $5 y=12 x+6$; find its equation.
9. Prove analytically that the diagonals of a square are of equal length, bisect each other, and are at right angles.
10. Prove analytically that the line joining the middle points of two sides of a triangle is parallel to the third side and equal to half its length.
11. Find the locus of the vertex of a triangle whose base is $2 a$ and the difference of the squares of whose sides is $4 c^{2}$. Trace the locus.
12. Find the equations of the lines from the vertex $(4,3)$ of the triangle of Ex. 4, trisecting the opposite side. What are the ratios of the areas of the resulting triangles?
13. A point moves so that the sum of its distances from the lines $y-3 x+11=0$ and $7 x-2 y+1=0$ is 6 . Find the equation of its locus. Draw the figure.
14. Find the equation of the path of the moving point of Ex. 13, if the distances from the fixed lines are in the ratio $3: 4$.
15. Solve examples 13 and 14 , taking the given lines as axes.
16. The point $(2,9)$ is the vertex of an isosceles right triangle whose hypotenuse is the line $3 x-7 y=2$. Find the other vertices of the triangle.
17. The axes of coördinates being inclined at the angle $60^{\circ}$, find the equation of a line parallel to the line $x+y=3 a$, and at a distance $\frac{a \sqrt{8}}{2}$ from it.
18. Find the point of intersection of the lines

$$
\rho=\frac{2 a}{\cos \left(\theta-\frac{\pi}{2}\right)} \text { and } \rho \cos \left(\theta-\frac{\pi}{6}\right)=a
$$

For what value of $\theta$, in each line, is $\rho=\infty$ ? At what angles do these lines cut their polar axes? Find the angle between the lines. Plot these lines.
19. Find the equation of a straight line through the intersection of $y=7 x-4$ and $2 x+y=5$, and forming with the $x$-axis the angle $\frac{\pi}{3}$.
20. Find the equation of the locus of a point which moves so as to be always equidistant from the points $(2,1)$ and $(-3,-2)$.
21. Find the equations of the liscus of a point which moves sio as to lee alwaye erpulitistant from thee points $(0,0)$ and $(3,2)$. Show that tho proints $(0,0),(3,2)$, and $(1,-1)$ are the vertices of an incobeles triangle.
22. Find the center and radius of the circle cireumactil al abous the intanglo whome vertions are the puints $(2,1),(3,2),(-4,7)$.
23. Fimi analytically the equation of the locus of the verters of a sitangle having fis base and area constant.
24. Prove analytically that the locus of a point equidintant from iwo given points $\left(x_{1}, y_{1}\right)$ and $\left(r_{5}, y_{2}\right)$ is the perpeoticular bisector of the lise joining the given points.
25. The bise of a triangle is of length 5 , and is given in position: the difference of the syuares of the other swo sides is 7; find the equartious of the locus of its vertex.
26. What limes are represented by the equations:
(a) $x^{2} y=x y^{2}$;
(ß) $11 x^{2}-5 x y-y^{2}=0$;
(y) $x y=0$ ?
27. What must be the ralue of $e$ in order that the lines $3 x+y-2=0$. $2 x-y-3=0$, and $5 x+2 y+c=0$ shall pass through a common point?
20. By finding the area of the triangle formed by the three points $(3 a, 0),(0,3 b)$ and $(a, 2 b)$, prove that these three points are in a straight line. I'rove this also by showing that the third point is on the line joining the other two.
29. Fiml, by the method of Art. 39, the point of internection of the iwo lines $2 x-3 y+7=0$ and $4 x=6 y+2$; and interpret the result by means of Arts. 41 and 60 .
30. Prove ly Art. 10 ( cf . also Arts. 11 and 60), that the equations of two parallel lines differ ouly in the constant term.
31. Find the equations of two lines each drawn through the point (1. 3), and forming with the axes a triangle whose ares is -8 .
32. Find the equation of a line through the proint $(2,-5)$, such that the prortion between the axes is divided by the given proint in the ratio 7: 8 .
33. Find the equation of the perpendicular emeted as the middle proint of the line joining ( 5,2 ) to the intersection of the two lines

$$
x+2 y=11 \text { and } 9 x-2 y=60
$$

34 A point moves so that the square of its distance from the origin equals twice the square of its distance from the $x$-axis ; find the equation of its locus.
35. Given the four lines

$$
x-2 y+2=0, x+2 y-2=0,3 x-y-3=0 \text { and } x+y+6=0 ;
$$

these lines intersect each other in six points; find the equations of the three new lines (diagonals), each of which is determined by a pair of the abore six points of intersection.
36. Find the points of intersection of the loci :

$$
\begin{aligned}
& \text { (a) } \rho \cos \left(\theta-\frac{\pi}{3}\right)=a \text { and } \rho \cos \left(\theta-\frac{\pi}{6}\right)=a \text {; } \\
& \text { ( } \beta \text { ) } \rho \cos \left(\theta-\frac{\pi}{2}\right)=\frac{3 a}{4} \text { and } \rho=a \sin \theta \text {. }
\end{aligned}
$$

If two sides of a triangle are taken as axes, the vertices are $(0,0)$, $\left(x_{1}, 0\right),\left(0, y_{2}\right)$. Prove analytically that:
37. the medians of a triangle meet in a point;
38. the perpendicular from each vertex to the opposite sides meet in a point;
39. the line joining the middle points of two sides of a triangle is parallel to the third side.
40. Show that the equation $56 x^{2}+441 x y-58 y^{2}-79 x-47 y+9=0$ represents the bisectors of the angles hetween the straight lines represented by $15 x^{2}-16 x y-48 y^{2}-2 x+16 y-1=0$.
41. Two lines are represented by the equation

$$
A x^{2}+2 I I x y+B y^{2}=0 .
$$

Find the angle between them.
42. Using the product of a side by half the altitude derive the formula [4] for the area of the triangle whose vertices are at the points $\left(x_{1}, y_{1}\right)$, $\left(x_{2}, y_{2}\right)$, and $\left(x_{3}, y_{3}\right)$. Wherein is this demonstration more general than that given in Art. 29?

## CHAPTER VI

## TRANSFORMATION OF COORDINATES

70. That the coordinates of a point which remains fixed is a plane are changed by changing the axes to which this fixed point is referred, is an immediate consequence of the detinition of coorrdinates.

It is also evident that the different hinds of eoördinates of any given point (Cartesian and polar, for example) are connected by definite relations if the elements of reference (the axes) are related in position. E.g., the point $Q$. when referred to the polar axis $O X$ and the pole $O$, has the coördinates $\left(5,30^{\circ}\right)$, but when it is referred to the rectangular axes $O X$ and
 OY the coordinates of this same point are $\left(\frac{8}{3}, \sqrt{3}\right)$; and generally, if $(\rho, \theta)$ be the coordinates of a point when referred to $O X$ and $O$, then $(\rho \cos \theta, \rho \sin \theta)$ are its cooirdinates when it is referred to the
rectangular axes $O X$ and $O Y$.
Again: while a curve remains fixed in a plane, its equation may often be greatly simplified by a judicious change of
the axes to which it is referred. E.g., the line $L_{1} L$, when referred to the axes $O X$ and $O Y$, has the equation

$$
y=\tan \theta \cdot x+b
$$

but when referred to the axes $O^{\prime} X^{\prime}$ and $O^{\prime} Y^{\prime}$, the former of which is parallel to the given line, its equation is $y=c$.

For these, and other reasons, in the study of curves and surfaces by the methods of analytic geometry, it will often be found advantageous to transform the equations from one set of axes to another.

It will be found that the coördinates of a point with reference to any given axes, are always connected by simple formulas with the coördinates of the same point when it is referred to any other axes. These relations or formulas for the various changes of axes are derived in the next few articles.

## I. CARTESIAN COÖRDINATES ONLY

71. Change of origin, new axes parallel respectively to the original axes. Let $O X$ and $O Y$ be the original axes, $O^{\prime} X^{\prime}$ and $O^{\prime} Y^{\prime}$ the new axes, and let the coördinates of the new origin when referred to the
 original axes be $h$ and $k$, i.e., $O^{\prime} \equiv(h, k)$, where $h=O A$ and $k=A O^{\prime}$. Also let $P$, any point of the plane, have the coördinates $x$ and $y$ when it is referred to the axes $O X$ and $O Y$, and $x^{\prime}$ and $y^{\prime}$ when it is referrea to the axes $O^{\prime} X^{\prime}$ and $O^{\prime} Y^{\prime}$.

Draw $M M^{\prime} P$ parallel to the $y$-axis ; then

$$
O M=O A+A M=O A+O^{\prime} M^{\prime},
$$

i.e.,
and similarly,

$$
\left.\begin{array}{l}
x=x^{\prime}+\boldsymbol{h},  \tag{23}\\
y=y^{\prime}+\boldsymbol{k},
\end{array}\right\}
$$

which are the equations (or formulas) of transformation from any given axes to new axes which are respectively parallel to the original ones, the new origin being the point $\theta^{\prime}=(h, k)$. These formulas, moreover, are independent of the angle between the axes.

As a simple illustration of the usefulness of such a change of axes, suppose the equation

$$
\begin{equation*}
x^{3}-2 h x+y^{2}-2 k y=a^{2}-h^{2}-k^{2} \tag{1}
\end{equation*}
$$

given, in which $x$ and $y$ are courdinates referred to the axes $O X$ and $O Y$.

Now let $P \equiv(x, y)$ be any point on the locus $L_{1} L$ of this equation, and let ( $x^{\prime}, y^{\prime}$ ) be the coordinates of the same point $P$ when it is referred to the axes $O^{\prime} X^{\prime}$ and $O^{\prime} Y^{\prime}$; then

$$
x=x^{\prime}+k \text { and } y=y^{\prime}+k .
$$

Substituting these values in the given equation for the $x$ and $y$ there involved, an equation in $x^{\prime}$ and $y^{\prime}$ is obtained which is satisfied by the coördinates of every point on $L_{1} L$, i.e., it is the equation of the same locus. The substitution gives:
$\left(x^{\prime}+h\right)^{2}-2 h\left(x^{\prime}+h\right)+\left(y^{\prime}+k\right)^{2}-2 k\left(y^{\prime}+k\right)=a^{2}-h^{2}-k^{2}$,
which reduces to

$$
x^{\prime 2}+y^{\prime 2}=a^{2} ;
$$

a much simpler equation than (1), but representing the same locus, merely referred to other axes.

## EXERCISES

1. What is the equation for the locus of $3 x-2 y=6$, if the origin be changed to the point $(4,3)$, -directions of axes unchanged?
2. What does the equation $x^{2}+y^{2}-4 x-6 y=18$ thecome if the origin be changed to the point $(2,8)$, -directions of axes unchanged?
3. What does the equation $y^{2}-2 x^{2}-2 y+6 x-3=0$ become when the origin is removed to ( 3,1 ), -directions of axes unchanged?
4. Find the equation for the straight line $y=3 x+1$ when the origin is removed to the point $(1,4)$, -directions of axes unchanged.
5. Construct appropriate figures for exercises 1 and 4.
6. Transformation from one system of rectangular axes to another system, also rectangular, and having the same origin : change of direction of axes.

Let $O X$ and $O Y$ be a given pair of rectangular axes, and let $O X^{\prime}$ and $O Y^{\prime}$ be a second pair, with $\angle X O X^{\prime}=\theta$, the

Fio. 58 angle through which the first pair of axes must be turned to come into coincidence with the second. Also let $P$, any point in the plane, have the coördinates $x$ and $y$ when it is referred to the first pair of axes, and $x^{\prime}$ and $y^{\prime}$ when referred to the second pair. The problem now is to express $x$ and $y$ in terms of $x^{\prime}, y^{\prime}$, and $\theta$. Draw the ordinates $M P, M^{\prime} P$, and $Q M^{\prime}$, and draw $M^{\prime} R$ parallel to the $x$-axis; then
i.e.,
and similarly

$$
O M=O Q+Q M=O M^{\prime} \cos \theta-M^{\prime} P \sin \theta,
$$

which are the required formulas of transformation from one pair of rectangular axes to another, having the same origin but making an angle $\theta$ with the first pair.

Note 1. These formulas are more easily obtained, - in fact, they can be read directly from the figure, - if one recalls Art. 17, and considers that the projection of $O P$ equals the projection of $O M+$ the projection of $M^{\prime} P$, upon $O X$ and $O Y$ in turn.

Note 2. The reader will observe that a combination of the transformation of Art. 71 with that of Art. 72 will transform from one pair of rectangular axes to any other pair of rectangular axes.

## EXERCISES

Tisn the axes through ant angler of 4.3 , and find the new envations for the following loci:

1. $x^{4}+y^{3}=10$;
2. $x^{2}=y^{3}=15$;
3. $y=x-1$;
4. $17 x^{2}-16 x y+17 y^{4}=225$.
5. If the axes are turned through the angle tant ${ }^{-1} 2$, what does the muation $4 x y-3 x^{3}=a^{3}$ become?
6. Transformation from rectangular to oblique axes, origin unchanged. Let $O X^{\prime}$ and $O Y$ be a given pair of rectangular axes, let $O X^{\prime}$ and $O Y^{\prime}$ be the new axes making an angle a with each other, and Let the angles $X \bar{O} X^{\prime}$ and $X O Y^{\prime}$ be denoted by $\theta$ and $\phi$, respectively. Also let $P$, any point in the
 plane, have the coördinates $x$ and $y$ when referred to the first pair of axes, and $x^{\prime}$ and $y^{\prime}$ when referred to the second prair.

Draw the ordinates $M P, M^{\prime} P$, and $Q M^{\prime}$, also draw $M^{\prime} R$ parallel to the $x$-axis.

Then $O M=O Q+Q M=O M^{\prime} \cos \theta+M^{\prime} P^{\prime} \sin (90-\phi)$;

$$
\left.\begin{array}{l}
x=x^{\prime} \cos \theta+y^{\prime} \cos \phi_{0} \\
y=x^{\prime} \sin \theta+y^{\prime} \sin \phi_{1}
\end{array}\right\}^{\circ}
$$

which are the required formulas of transformation from rectangular to ohlique axes having the same origin.

If $\omega=90^{\circ}$, and consequently $\phi=90^{\circ}+\theta$, then formulas [25] reduce to [24], and Art. 73, therefore, includes Art. 72 is a special case.

By first solving for $x^{\prime}$ and $y^{\prime}$, formulas [2i] may also be employed to transform from oblique to rectangular axes.

## EXERCISES

1. Given the equation $9 x^{2}-16 y^{2}=144$ referred to rectangular axes; what does this equation become if transformed to new axes such that the new $x$-axis makes the angle $\tan ^{-1}(-1)$, and the new $y$-axis the angle $\tan ^{-1}\left(\frac{1}{}\right)$, with the old $x$-axis, - origin unchanged?
2. If the old and new $x$-axes coincide, and the new axes are rectangular while the old axes are inclined at an angle of $60^{\circ}$, what are the equations of transformation from the old axes to the new? From the new axes to the old? Origin unchanged in each case.
3. If the first two of the three sides of a triangle whose equations are $2 y+x+1=0,3 y-x-1=0$, and $2 x+3 y=1$, are chosen as new axes, find the new equations of the sides.
4. Transformation from one set of oblique axes to another, origin unchanged. Let $O X$
 and $O Y$ be a given pair of axes, $O X^{\prime}$ and $O Y^{\prime}$ the new axes, and let the angles $X O Y$, $X^{\prime} O Y^{\prime}, X O X^{\prime}$, and $X O Y^{\prime}$ be denoted by $\omega, \omega^{\prime}, \theta$, and $\phi$, respectively. Also let $P$, any point in the plane, have the coördinates $x$ and $y$ when referred to the first pair of axes, and $x^{\prime}$ and $y^{\prime}$ when referred to the second pair.

Draw $M^{\prime} P$ parallel to $O Y^{\prime}, M P$ and $Q M^{\prime}$ parallel to $O Y$, and $M^{\prime} R$ parallel to $O X$.
Then, from the triangle $O Q M^{\prime}$,

$$
O Q=x^{\prime} \frac{\sin (\omega-\theta)}{\sin \omega} \text { and } Q M^{\prime}=x^{\prime} \frac{\sin \theta}{\sin \omega} \text {, }
$$

and from the triangle $R M^{\prime} P$,

$$
R M^{\prime}=y^{\prime} \frac{\sin (\phi-\omega)}{\sin \omega} \text { and } R P=y^{\prime} \frac{\sin \phi}{\sin \omega}
$$

But $O M=O Q-R M^{\prime}$, and $M P=Q M^{\prime}+R P$;

$$
\left.\begin{array}{l}
\therefore x=x^{\prime} \frac{\sin (\omega-\theta)}{\sin \omega}+y^{\prime} \frac{\sin (\omega-\phi)}{\sin \omega} \\
\text { and } y=x^{\prime} \frac{\sin \theta}{\sin \omega}+y^{\prime} \frac{\sin \phi}{\sin \omega}
\end{array}\right\}
$$

which are the required formulas of transformation from one pair of oblique axes to another having the same origin.

Sors. If it is desired to change the origin, and also the direction of the axes, the necessary formulas may be obtained by combining Art. 71 with Art. 72, Art. 73, or Art. 74, depending upon the given and required axes.

## EXERCISES

1. Show, by specializing some of the angles es, ©, $\theta$, and $\phi$ in Art. it, that formulas [26] include boths [25] and [24] as special cases.
2. The equation of a certain locus, when referred to a pair of axes that are inclined to each other at an angle of $60^{3}$, is $\overline{7} x^{2}-2 x y+4 y^{3}=5$; what will this equation become if the axes are each turned through an angle of $30^{\circ}$ ? What if the $x$-axis is turned throught the angle - $30^{\circ}$ while the $y$-axis is lurned through $+30^{\circ}$ ?
3. The degree of an equation in Cartesian coordinates is not changed by transformation to other axes. Every formula of transformation obtained ([23] to [26]) has replaced $x$ and $y$, respectively, by expressions of the first degree in the new coordinates $a^{\prime}, y^{\prime}$. Therefore any one of these transformations replaces the terms containing $x$ and $y$ by expressions of the same degree, and so cannot raise the degree of the given equation. Neither can any one of these transformations lover the degree of the given equation; for if it did,
[^23]```
тA%.ax. ©%ON.-9
```

then a transformation back to the original axes (which must give again the original equation) would raise the degree, which has just been shown to be impossible; hence all these transformations leave the degree of an equation unchanged.

## IL POLAR COÖRDINATES

76. Transformations between polar and rectangular systems. (1) Transiormation from a rectangular to a polar system, and vice versa, the origin and
 $x$-axis coinciding respectively with the pole and the initial line. Let $O X$ and $O Y$ be a given set of rectangular axes, and let $O X$ and $O$ be the initial line and pole for the system of polar coördinates. Also let $P$, any point in the plane, have the coördinates $x$ and $y$ when referred to the rectangular axes, and $\rho$ and $\theta$ in the polar system (Fig. 61), then

$$
O M=O P \cos X O P
$$

i.e.,
similarly,

$$
\left.\begin{array}{l}
x=\rho \cos \theta ;  \tag{27}\\
y=\rho \sin \theta .
\end{array}\right\}
$$

These are the required formulas of transformation when, but only when, the rectangular and polar axes are related as above described.

Conversely, from formulas [27], or directly from Fig. 61,
$\rho=\sqrt{x^{2}+y^{2}}, \cos \theta=\frac{x}{\sqrt{x^{2}+y^{2}}}$, and $\sin \theta=\frac{y}{\sqrt{x^{2}+y^{2}}}$.
which are the required formulas of transformation from polar to rectangular axes, under the above conditions.
(2) Siame as (1) except that the initial line Ull mation an angle a with the x-axis. It is at onee evident that the formulas of transformation for this case are:
and $\left.\begin{array}{l}x=\rho \cos (\theta+\varepsilon) . \\ y=\rho \sin (\theta+\varepsilon)_{0}\end{array}\right\} \ldots[29]$
The converse formulas for this case are:

$$
\begin{equation*}
\rho=\sqrt{x^{2}+y^{2}} \tag{30}
\end{equation*}
$$

and $\theta=\cos ^{-1}\left(\frac{x}{\sqrt{x^{3}+y^{2}}}\right)-a=\sin ^{-1}\left(\frac{y}{\sqrt{x^{3}+y^{2}}}\right)-u$.
(3) Tranşformation from any Cartenian system to any pular syatcm. Transform first to rectangular axes whose origin is the proposed pole; this is accomplished by Arts. 71 and 73. Then by formula [27] or [29] transform from the rectangular Cartesian to the polar cobrdinates.

## EXERCISES

Change the following to the corresponding polar equations; draw a figure showing the two related systems of axes in each case. Take the pole at the origin, the polar axis coincident with the axis of $x$, in exercises 1 to 4 .

1. $x^{2}+y^{3}=a^{3}$.
2. $y^{2}-x+2 \mathrm{ay}=0$.
3. $x^{2}+y^{2}=9\left(x^{2}-y^{2}\right)$.
4. $y=x \tan a$.
5. $x-\sqrt{3} y+2=0$, taking pole at origin, polar axis making the angle $60^{\circ}$ with the $x-a x i s$.
6. $x^{2}-y^{3}-4 x-6 y-34=0$, taking the pole at the pwint $(2,-3)$, and the polar axis parallel to the eaxis.

Change the following to corresponding rectangular equations. Take the origin at the pole and the x-axis colncident with the polar asis.
7. $\rho=a$.
8. $\rho^{2} \cos 2 \theta=a^{2}$.
9. $\rho^{2} \sin 2 \theta=10$.
10. $p^{2}=a^{2} \sin 2 \theta$.

Sugarstios. In Ex. 10 multiply by $\rho^{2}$ and sulatitute $2 \sin \theta \cos \theta$ for $\sin 2 \theta$; the equation then becomes $p^{6}=20^{3} p^{6} \sin \theta \cos \theta$.
11. $p=6 \cos \theta$.
12. $\theta=3$ Lan ${ }^{-1}$.
13. $\rho^{\frac{1}{2}} \operatorname{ens} \frac{\theta}{2}=k^{3}$.

## EXAMPLES ON CHAPTER VI

1. Find the equation of the locus of $2 x y-7 x+4 y=0$ referred to parallel axes through the point $\left(-2, \frac{3}{2}\right)$.
2. Transform the equation $x^{2}-4 x y+4 y^{2}-6 x+12 y=0$ to new rectangular axes making an angle tan ${ }^{-1} \frac{1}{1}$ with the given axes.
3. Transform $y^{2}-x y-5 x+5 y=0$ to parallel axes through the point $(-5,-5)$. Draw an appropriate figure.
4. Transform the equation of example 3 to axes bisecting the angles between the old axes. Trace the locus.
5. To what point must the origin be moved (the new axes being parallel to the old) in order that the new equation of the locus

$$
2 x^{2}-5 x y-3 y^{2}-2 x+13 y-12=0
$$

shall have no terms of first degree?
Solution. Let the new origin be $(h, k)$; then $x=x^{\prime}+h, y=y^{\prime}+k$, and the new equation is

$$
\begin{gathered}
2\left(x^{\prime}+h\right)^{2}-5\left(x^{\prime}+h\right)\left(y^{\prime}+k\right)-3\left(y^{\prime}+k\right)^{2}-2\left(x^{\prime}+h\right)+13\left(y^{\prime}+k\right)-12=0 \\
\text { i.e., } \quad 2 x^{\prime 2}-5 x^{\prime} y^{\prime}-3 y^{\prime 2}+(4 h-5 k-2) x^{\prime}-(5 h+6 k-13) y^{\prime} \\
+2 h^{2}-5 h k-3 k^{2}-2 h+13 k-12=0
\end{gathered}
$$

but it is required that the coefficients of $x^{\prime}$ and $y^{\prime}$ shall be 0 ; i.e., $h$ and $k$ are to be determined so that

$$
4 h-5 k-2=0
$$

and

$$
5 h+6 k-13=0
$$

hence

$$
h=y \text { and } t:=\frac{s}{7}
$$

Therefore the new origin must be at the point $\left(\frac{y}{4}, \frac{f}{7}\right)$, and the new equation is

$$
2 x^{\prime 2}-5 x^{\prime} y^{\prime}-3 y^{2}-8=0
$$

6. The new axes being parallel to the old, determine the new origin so that the new equation of the locus

$$
x^{2}-3 x y+y^{2}+10 x-10 y+21=0
$$

shall have no terms of first degree.
7. Transform the equations $x+y-3=0$ and $2 x-3 y+4=0$ to parallel axes having the point of intersection of these lines as origin.
8. Transform the equation $\frac{x}{4}+\frac{y}{6}=1$ to new rectangular axes through the point $(2,3)$, and making the angle $\tan ^{-1}\left(-\frac{3}{2}\right)$ with the old axes.
9. Through what angle must the axes be turned that the new equation of the line $6 x+4 y-21=0$ shall have no $y$-term? Show this geometrically, from a figure.
10. Through what angle must the axes the turned in oriter that the new equation of the lime $0 x+4 y=21$ shall have no zterm? Show analytieally (ef. also examples 8 and 9 ).

Solvtios. Lat $\theta$ be the required angle; then the equations of trame furmation are

$$
x=z^{\prime} \cos \theta-y^{\prime} \sin \theta \text { and } y=x^{\prime} \sin \theta+y^{\prime} \cos \theta ;
$$

and the new equation is

$$
(6 \cos \theta+4 \sin \theta) x^{\prime}-(8 \sin \theta-4 \cos \theta) y^{\prime}=24 ;
$$

but it is required that the coesficient of $a$ bo 0 ,
$\therefore \quad 6 \cos \theta+4 \sin \theta=0$, i.e., $\tan \theta=-\frac{1}{6}$;
whence $\quad \theta=\tan ^{-1}(-1)$,
and the equation becomes

$$
(6 \sin \theta-4 \cos \theta) y^{\prime}+24=0
$$

which reduces to

$$
\begin{aligned}
& \frac{26}{\sqrt{13}} y^{\prime}+24=0 \\
& \sqrt{18} y^{\prime}+12=0 .
\end{aligned}
$$

11. Through what angle must the axes be turned to remove the z.term from the equation of the locus $A x+B y+C=0$ ? to remove the yterm?
12. Show that to remove the ry-term from the equation of the locus, $2 x^{2}-5 x y-3 y^{2}=8$ (cf. Ex. 5), the axes must be turned through the angle $\theta=67^{\circ} 30^{\circ}$, i.e., so that tan $2 \theta=-1$. What is the new equation?
13. Through what angle must a pair of rectangular axes be turned that the new $x$-axis may pass through the point $(-2,-5)$ ?
14. What point must be the new origin, the direction of axes being unchanged, in order that the new equation of the line $A x+B y+C=0$ shall have no constant term?
15. To what point, as origin of a pair of parallel axes, must a transformation of axes be made in order that the new equation of the locus, $x y-y^{3}-x+y=0$, shall have no terms of first degree? Construet the locus.
16. Find the new origin, the direction of axes remaining unchanged, so that the equation of the locus, $x^{2}+x y-3 x-y+2=0$, shall have no constant term. Construct the figure.
17. Transform the equation $4 x^{3}+2 \sqrt{3} r y+2 y^{2}=1$ to new rectangular axes making an angle of $30^{\circ}$ with the given axes, -origin unchanged.
18. Transform $y^{2}=8 x$ to new rectangular axes having the point ( 18,12 ) as origin, and making an angle cot ${ }^{-1} 3$ with the old.
19. Transform to rectangular coordinates, the pole and initial line being coincident with the origin and $x$-axis, respectively:

$$
\text { (a) } \rho^{2}=a^{2} \cos 2 \theta, \quad \text { ( } \beta \text { ) } \rho^{2} \cos 2 \theta=a^{2}, \quad \text { (y) } \rho=k \sin 2 \theta
$$

Transform to polar coordinates, the $x$-axis and initial line being coincident:
20. $\left(x^{2}+y^{2}\right)^{2}=k^{2}\left(x^{2}-y^{3}\right)$, the pole being at the point $(0,0)$;
21. $x^{2}+y^{2}=7 \mathrm{ax}$, pole being at the point $(0,0)$;
22. $x^{2}+y^{2}=16 x$, the pole being at the point $(8,0)$.
23. Transform the equation $y^{2}+4 a y \cot 30^{\circ}-4 a x=0$ to an oblique system of coordinates, with the same origin and $x$-axis, but the new $y$-axis at an angle of $30^{\circ}$ with the old $x$-axis.
24. Transform the equation $\frac{x^{2}}{16}+\frac{y^{2}}{9}=1$, to new axes, making the positive angles $\tan ^{-1} \frac{1}{4}$ and $\tan ^{-1}\left(-\frac{8}{4}\right)$, respectively, with the old $x$-axis, the origin being unchanged.
25. Transform the equation
$3 x^{2}+10 \sqrt{3} x y-7 y^{2}=(18-30 \sqrt{3}) x+(42+30 \sqrt{3}) y+(42+90 \sqrt{3})$ to the new origin $(3,-3)$, with new axes making an angle of $30^{\circ}$ with the old.
26. Transform the equation $3 x^{2}+8 x y-3 y^{2}=0$ to the two straight lines which it represents, as new axes.
27. Transform $\frac{x^{2}}{25}-\frac{y^{2}}{9}=1$ to the straight lines $\frac{x^{2}}{25}-\frac{y^{2}}{9}=0$, as new axes.
28. Transform to polar coördinates the equation $y^{2}(2 a-x)=x^{3}$.
29. Transform to rectangular coördinates the equation

$$
\rho=a(\cos 2 \theta+\sin 2 \theta)
$$

30. Prove the formula for the distance in polar coördinates [1] by transformation of the corresponding formula [2] in rectangular coordinates.
31. Transform the equation $x \cos a+y \sin a=p$ to polar coördinates.

## CHAPTER VII

## THE CIRCLE

## Special Equation of the Second Degree

$$
A x^{2}+A y^{2}+2 G x+2 F y+C=0
$$

77. It must be kept clearly in mind that one of the chief aims of an elementary course in Analytie Geometry is wo teach a new method for the study of geometric properties of eurves and surfaces. Power and facility in the use of such a new method are best acquired by applying it first to those loci whose properties are already best understood. Accord. ingly, the straight line having already been studied in Chapter $V$, the circle will next be examined.

It will appear later that the circle is only a special case of the conio sections already referred to in Art. 48, and might, therefore, be advantageously studied after the general projerties of those curves had been examined; the present order is adopted, however, because the student is already familiar with the chief properties of the circle.

In solving the exereises of this chapter tho student should use the analytie methods, even when purely geometric methorls might suffice, - he is learning to use a new instrument of investigation, and is not merely studying the properties of the circle.
78. The circle: its definition, and equation. The circle may be defined as the path traced by a point which moves in such a way as to be always at a constant distance from a given fixed point. This fixed point is the center, and the constant distance is the radius, of the circle.

To derive the equation from this definition, let $C \equiv(h, k)$ be the center, $r$ the radius, and $P \equiv(x, y)$ any point on the
 curve. Also draw the ordinates $M_{1} C$ and $M P$, and the line $C R$ parallel to the $x$-axis; then
$C P=r ; \quad$ [geometric equation] but (Art. 26),

$$
C P=\sqrt{(x-h)^{2}+(y-k)^{2}},
$$

hence $\sqrt{(x-h)^{2}+(y-k)^{2}}=r$;
i.e.,

$$
(\boldsymbol{x}-\boldsymbol{h})^{\mathbf{2}}+(\boldsymbol{y}-\boldsymbol{k})^{2}=\boldsymbol{r}^{2}, \quad \text {. . . }[31]
$$

which is the equation of the circle whose radius is $r$, and whose center has the coördinates $h$ and $k$.

With given fixed axes, equation [31] may, by rightly choosing $h, k$, and $r$, represent any circle whatever ; it is, therefore, called the general equation of the circle. Of its special forms one is, because of its very frequent application, particularly important; this form is the one for which the center coincides with the origin : in that case $h=k=0$, and equation [31] becomes

$$
\begin{equation*}
x^{2}+y^{2}=r^{2} .1 \tag{32}
\end{equation*}
$$

- Equation [31] may be written in the form

$$
(x-h)^{2}+(y-k)^{2}-r^{2}=0
$$

the first member then becomes positive if the coördinates of any point outsicle of the circle are substituted for $x$ and $y$, it becomes negative for a point inside of the circle, and zero for a point on the circle. Hence the circle may be regarded as the boundary which separates that part of the plane for which the function $(x-h)^{2}+(y-k)^{2}-r^{2}$ is positive from the part for which this function is negative. The inside of the circle may therefore be called its negatire side, while the outside is its positive side (cf. foot-note, Art. 43).
$\dagger$ If one is unrestricted in his choice of axes, then an equation of the form of [32] may represent any circle whatever, - the axes need merely be chosen perpendicular to each other and through its center; - equation [31] is more general in that, the rectangular axes being determined by other considerations, it may still represent any circle whatever.

## EXERCISES

Finst construet the circle, then find ite ertuation, beiog givens:

1. the center $(5,-3)$, the radius if
2. Lhee centeer $(0,2)$, the radius If
3. Live eventer $(3,-3)$, the radius 3;
4. the eonter $(1,0)$, the radiun 5 ;
5. the center $(-1,0)$, the radius 1 .
6. How are circles related for which $h$ and $t$ are the same, while $r$ is different for each? for which $h$ and $r$ are the same, while $t$ differs for each ?
7. What form does the equation of the circle assume when the center is on the a-axis and the origin on the circumference? when the circle couches each axis and has its center in quadrant II?
8. In rectangular coordinates every equation of the form $x^{2}+y^{2}+2 G x+2 \boldsymbol{F} y+\boldsymbol{C}=\mathbf{0}$ represents a circle. The equafions of the circles already obtained (equations [31] and [32], as well as the answers to examples 1 to 5 and 7) are all of the form

$$
\begin{equation*}
x^{3}+y^{3}+2 G x+2 F y+C=0 \tag{1}
\end{equation*}
$$

it will now be shown that, for all values of $G, F$, and $C$, for which the locus of equation (1) is real, this equation represents a circle.

To prove this it is only necessary to complete the square in the $x$-terms and in the $y$-terms, by adding $f^{2}+F^{2}$ to each member of equation (1), and then transpose $C$ to the second member. Equation (1) may then be written in the form

$$
\begin{align*}
(x+G)^{2}+(y+F)^{2} & =G^{2}+F^{2}-C \\
& =\left(\sqrt{W^{3}+F^{2}-C^{2}}\right)^{2} \tag{2}
\end{align*}
$$

which is (cf. equation [31]) the equation of a circle whose center is the point $\left(-G_{,}-F\right)$, and whose radius is

$$
\sqrt{G^{6}+f^{\prime 2}-C}
$$

Note 1. This circle is real ouly if $G^{2}+F^{2}-C>0$; for, if

$$
G^{2}+F^{2}-C<0,
$$

its square root is imaginary, and no real values of $x$ and $y$ can then satisfy equation (2); while if $G^{2}+F^{2}-C=0$, then equation (2) reduces to

$$
\begin{equation*}
(x+G)^{2}+(y+F)^{2}=0, . \tag{3}
\end{equation*}
$$

which may be called the equation of a "point circle," since the coordinates of hut one real point, viz. ( $-G,-F$ ), will satisfy equation (3). If, however, $G^{2}+F^{2}-C>0$, then equation (1) represents a real circle for all values of $G, F$, and $C$, sulject to this single limitation.

Note 2. Every equation of the form $A x^{2}+A y^{2}+2 G x+2 F y+C=0$ represents a circle, for, by Art. 88 , this equation has the same locus as has $x^{2}+y^{2}+2 \frac{G}{A} x+2 \frac{F}{A} y+\frac{C}{A}=0$, and this last equation is of the form of equation (1).

Hence, interpreted in rectangular coördinates, every equation of the second degree from which the term in $x y$ is absent, and in which the coefficient of $x^{2}$ equals that of $y^{2}$, represents a circle.
80. Equation of a circle through three given points. By means of equation [31], or of the equation

$$
\begin{equation*}
x^{2}+y^{2}+2 G x+2 F y+C=0, \tag{1}
\end{equation*}
$$

which has been shown in Art. 79 to be its equivalent, the problem of finding the equation of a circle which shall pass through any three given points not lying on a straight line can be solved; i.e., the constants $h, k$, and $r$, or $G, F$, and $C$, may be so determined that the circle shall pass through the three given points.

To illustrate : let the given points be $(1,1),(2,-1)$, and (3,2), and let $x^{2}+y^{2}+2 G x+2 F y+C=0$ be the equation of the circle that passes through these points; to find the values of the constants $G, F$, and $C$. Since the point ( 1,1 ) is on this circle, therefore (cf. Art. 35),

$$
1+1+2 G+2 F+C=0
$$

similarly, $\quad 4+1+4 Q-2 F+C=0$,
and

$$
9+1+6 G+4 F+C=.0 .
$$

These equations give: $G=-\frac{1}{2}, F=-\frac{1}{1}$, and $C=4$. substituting these values, the equation of the required circle becomes

$$
x^{2}+y^{2}-5 x-y+4=0 ;
$$

its center is at the point $\left(\frac{1}{2}, \frac{1}{2}\right)$, while its radius is $\frac{1}{2} \sqrt{10}$.
Note. The fact that the most general equation of the circle contains thres parameters ( $h, 1$, and $r$, or $G, F$, and $C$, above) corresponds to the property that a circle is uniquely determined by three of its points.

## EXERCISES

Find the radii, and the courdinates of the centens, of the following circles; also, draw the circles.

1. $x^{2}+y^{2}-4 x-8 y-41=0$. 4. $2\left(x^{2}+y^{2}\right)=7 y$.
2. $8 x^{2}+3 y^{3}-3 x-7 y+1=0$.
3. $a x^{6}+a y^{2}=b x+c y$.
4. $x^{2}+y^{2}=3(x+3)$.
5. $(x+y)^{2}+(x-y)^{3}=8 a^{2}$.
6. What loci are represented by the equations
and

$$
\begin{aligned}
(x-k)^{2}+(y-k)^{2} & =0 \\
x^{2}+y^{2}-2 x+6 y+38 & =0 ?
\end{aligned}
$$

Find the equation of the circle through the pointas
8. $(1,2),(3,-4)$, and ( $5,-6)$;
9. $(0,0),(a, b)$, and $(b, a)$;
10. $(-0,-1),(0,1)$, and $(1,0)$;
11. $(10,2),(3,3)$, and having the radius 5 .

12 Find the equation of the circle which has the line joining the points $(3,4)$ and $(-1,2)$ for a diameter.
13. Find the equation of the circle which touches each axis, and pases through the point $(-2,3)$.
14. A circle has its center on the line $3 x+4 y=7$, and touches the two lines $x+y=3$ and $x-y=3$; find its equation, radius, and center; also draw the circle.

## SECANTS, TANGENTS, AND NORMALS

81. Definitions of secants, tangents, and normals. A straight line will, in general, intersect any given curve in two or more

Fig. 64. distinct points ; it is then called a secant line to the curve. Let $P_{1}$ and $P_{2}$ be two successive points of intersection of a secant line $P_{1} P_{2} Q$ with a given curve $L P_{1} P_{2} \ldots K$; $X$ if this secant line be rotated about the point $P_{1}$ so that $P_{2}$ approaches $P_{1}$ along the curve, the limiting position $P_{1} T$ which the secant approaches, as $P_{2}$ approaches coincidence with $P_{1}$, is called a tangent to the curve at that point. This conception of the tangent leads to a method, of extensive application, for deriving its equation, - the socalled "secant method." *

Since the points of intersection of a line and a curve are found (Art. 39) by considering their equations as simultaneous, and solving for $x$ and $y$, it follows that, if the line is tangent to the curve, the abscissas of two points of intersection, as well as their ordinates, are equal. Therefore, if the line is a tangent, the equation obtained by eliminating $x$ or $y$ between the equation of the line and that of the curve must have a pair of equal roots.

If the given curve is of the second degree, then the equation resulting from this elimination is of the second degree, and the test for equal roots is well known (Art. 9) ; but if the given equation is of a degree higher than the second, other methods must in general be used.

A straight line drawn perpendicular to a tangent and

[^24]through the point of tangency is called a normal line to the curve at that point. Thus, in Fig. 64, $P_{1} P_{3}, P_{1} P_{3}$ are secants, $P_{1} T$ is a tangent, and $P_{1} N$ a normal to the curve at $P_{1}$.

## B2. Tangents: Illuntrative examples.

(1) To find the equation of that langent to the circle $x^{3}+y^{3}=5$ which makes an angle of $45^{\circ}$ with the $z$-axis. Since this line makes an angle of $45^{\circ}$ with the $x$-axis its equation is $y=a+b$, where $b$ is to bo determined so that this line shall touch the circle.

Clearly, from the figure, there are two values of $b\left(O B_{1}\right.$ and $\left.O B_{2}\right)$ for which this lime will be tangent wo the efrele. Aceording to Art. 81, these 1.alues of $b$ are thine which make the two prints of intersection of the line and the cifele beeome coincident.

Considering the squations $x^{2}+y^{2}=5$ and $y=a$ \& $b$ simultaneous, and eliminating $y$, the resulting equation in $x$ is $x^{2}+(x+b)^{2}=5$, i.e., $2 x^{2}+2 b x+b^{2}-5=0$.
The roots of this equation will become equal, i.s., the atscissas of the points of ithersection will become equal (ArL. 0),

Fra.6s. if $b^{3}-2(b-5) \cong 0$, i.e, if $b \doteq \pm \sqrt{10}$.

The equations of the two required tangent lines are, therefore,

$$
y=x+\sqrt{10}, \text { and } y=x-\sqrt{10}
$$

(2) To find the equations of those tangents to the circle $x^{2}+y^{2}=6 y$ that are parallel to the line $x+2 y+11=0$.

The equation of a line paraflet to $x+2 y+11=0$ is $x+2 y+t=0$. where is is an artitrary constant (Art. 6\%), and this line will become tangent to the cirele, if the value of the constant it he so cbosen that the two points in which the line meets the circle shall beeome colncident.

Comsidering the equations $x^{2}+y^{3}=6 y$ and $x+2 y+5=0$ simultareous, and eliminating $x$, the resulting equation in $y$ is

$$
(-t-2 y)^{2}+y^{2}=6 y \text {, i.e., } 5 y^{2}+(1 t-6) y+k^{3}=0 \text {. }
$$

The two values of $y$ will become equal if (Art. 9)

$$
(4 k-6)^{2}-90 l^{2} \doteq 0 \text {, i.e., if } k^{2}+12 k-9 \doteq 0
$$

i.s. it

$$
1 \doteq-6 \pm 8 \sqrt{5}
$$

and the two required tangent lines are:

$$
x+2 y-6+3 \sqrt{5}=0, \text { and } x+2 y-6-3 \sqrt{3}=0
$$

## EXERCISES

Find the equations of the tangents:

1. to the circle $x^{2}+y^{2}=4$, parallel to the line $x+2 y+3=0$;
2. to the circle $3\left(x^{2}+y^{2}\right)=4 y$, perpendicular to the line $x+y=7$;
3. to the circle $x^{2}+y^{2}+10 x-6 y-2=0$, parallel to the line $y=2 x-7$;
4. to the circle $x^{2}+y^{2}=r^{2}$, and forming with the axes a triangle whose area is $r^{2}$.
5. Show that the line $y=x+c \sqrt{2}$ is, for all values of $c$, tangent to circle $x^{2}+y^{2}=c^{2}$; and find, in terms of $c$, the point of contact.
6. Prove that the circle $x^{2}+y^{2}+2 x+2 y+1=0$ touches both coördinate axes; and find the points of contact.
7. For what values of $c$ will the line $3 x-4 y+c=0$ touch the circle $x^{2}+y^{2}-8 x+12 y-44=0$ ?
8. For what value of $r$ will the circle $x^{2}+y^{2}=r^{2}$ touch the line $y=3 x-5$ ?
9. Prove that the line $a x=b(y-b)$ tonches the circle $x(x-a)$ $+y(y-b)=0$; and find the point of contact.
10. Three tangents are drawn to the circle $x^{2}+y^{2}=9$; one of them is parallel to the $x$-axis, and together they form an equilateral triangle. Find their equations, and the area of the triangle.
11. Equation of tangent to the circle $x^{2}+y^{2}=r^{2}$ in terms of its slope. The equation of the tangent to a given circle, in terms of its slope, is found in precisely the same way as that followed in solving (1) of Art. 82. Let $m$ be the given slope of the tangent, then the equation of the tangent is of the form

$$
\begin{equation*}
y=m x+b \tag{1}
\end{equation*}
$$

wherein $b$ is a constant which must be so determined that line (1) shall intersect the circle

$$
\begin{equation*}
x^{2}+y^{2}=r^{2} \tag{2}
\end{equation*}
$$

in two coincident points.

Niminating $y$ between equations (1) and (2) gives
i.e.,

$$
\begin{aligned}
& r^{2}+(m x+b)^{2}=r^{3} \\
& r^{2}\left(1+m^{2}\right)+2 b m x+b^{2}-r^{2}=0
\end{aligned}
$$

and the two values of $x$ uhtained from this equation will become equal (Art. 9) if

$$
\begin{gathered}
(m b)^{2}-\left(1+m^{2}\right)\left(b^{2}-r^{2}\right) \doteq 0, \\
b \doteq \pm r \sqrt{1+m^{2}}
\end{gathered}
$$

i.e., if

Substituting this value of $b$ in equation (1), it beoomes

$$
\left.y=m x \pm r \sqrt{1+m^{x}}, \quad \text {. . } \quad \text {. } 38\right]
$$

which is then, for all values of $m$, tangent to the circle ( 2 ).
This equation [38] enables one to write down immediately the equation of a tangent, of given slope, to a circle whose ecuter is at the origin.

Eg., to find the equation of the tangent whose sloper $m=1=$ tan $45^{\circ}$. to the circle $x^{3}+y^{2}=5$, it is only neeessary to sulbstitute 1 for $m$ and $\sqrt{5}$ for $r$ in equation [33]. This gives as the required equation $y=x \pm \sqrt{10}$ [cf. (1) Art. 82].

Notr 1. If the center of the given circle is not at the origin, i.e., if its equation is of the form $x^{2}+y^{2}+2 G i x+2 F y+C=0$, instead of $r^{2}+y^{2}=r^{2}$, then the same reasoning as that employed ahove would lead to

$$
y+F=m(x+G) \pm \sqrt{G^{6}+F^{2}-C} \cdot \sqrt{1+m^{2}} \cdot \cdot[34]
$$

as the equation of the required tangent.
This equation might have been obtained also by first transforming then equation $x^{3}+y^{2}+2 G x+2 F y+C=0$ to parallel axes throught the print ( $-G,-F$ ); this would have given $x^{2}+y^{2}=\sigma^{2}+F-C=r^{2}$ as the equation of the same circle, but now referred to axes throught its crnter. Referred to these new axes $y^{\prime}=m x^{\prime} \pm r \sqrt{1+m^{2}}$ (see eq. [35]) is, for all values of m , tangent to this circle; transforming this last equation back to the original axes, i.e., sulartituting for $x^{\prime}, y^{\prime}$, and $r$ their equals, viz., $x+G, y+F$, and $\sqrt{G^{2}+F^{3}-C}$, it lecomes

$$
y+F=m(x+G) \pm \sqrt{G^{2}+F^{2}-c^{3}} \cdot \sqrt{1+m^{2}}
$$

[^25]as before, which is, for all values of $m$, tangent to the circle whose center is at the point $(-G,-F)$ and whose radius is $\sqrt{G^{2}+F^{2}-C}$.

Note 2. Because of its frequent occurrence, it is useful to memorize equation [33]. On the other hand, it is not recommended that equation [34] be memorized, but it should be carefully worked out by the student. Instead of employing either of these formulas, however, the student may always attack the problems directly, as was done in Art. 82.

## EXERCISES

Find the equations of the lines which are tangent:

1. to the circle $x^{2}+y^{2}=16$, and whose slope is 3 ;
2. to the circle $x^{2}+y^{2}=4$, and which are parallel to the line $x+2 y$ $+3=0$ (cf. Ex. 1, Art. 82);
3. to the circle $x^{2}+y^{2}=9$, and which make an angle of $60^{\circ}$ with the $x$-axis; with the $y$-axis;
4. to the circle $x^{2}+y^{2}=25$, and which are perpendicular to the line joining the points $(-3,7)$ and $(7,5)$;
5. to the circle $x^{2}+y^{2}=2 x+2 y-1$, and whose slope is -1 .
6. Equation of tangent to the circle in terms of the coördinates of the point of contact: the secant method.
(a) Center of the circle at the origin. Let $P_{1} \equiv\left(x_{1}, y_{1}\right)$ be the point of tangency, on the given circle

$$
\begin{equation*}
x^{2}+y^{2}=r^{2} \tag{1}
\end{equation*}
$$

Through $P_{1}$ draw a secant line $L M$, and let $P_{2} \equiv\left(x_{2}, y_{2}\right)$ be its other point of intersection with the circle. If the
 point $P_{2}$ moves along the circle until it comes into coincidence with $P_{1}$, the limiting position of the secant $L M$ is the tangent $P_{1} T$. (Art. 81.)

The equation of the line $L M$ is

$$
y-y_{1}=\frac{y_{2}-y_{1}}{x_{2}-x_{1}}\left(x-x_{1}\right) \ldots \text { (2) }
$$

If now $P_{2}$ approaches $P_{1}$ until
$x_{1}=x_{1}$ and $y_{2}=y_{1}$, equation (2) takes the indeterminate form

$$
\begin{equation*}
y-y_{1}=\frac{0}{v}\left(x-x_{1}\right) \tag{8}
\end{equation*}
$$

This indeterminateness arises because account has not yet been taken of the path (or direction) by which $P_{2}$ shall approach $I_{3}$, and it disappears immediately if the condition that $P_{3}$ is to approach $P_{1}$ along the circle (1) is introduced.

Since the fixed point $P_{1}$ is on the circle (1), therefore

$$
\begin{equation*}
x_{1}^{2}+y_{1}^{2}=r^{2} ; \tag{4}
\end{equation*}
$$

and since $P_{s}$, while approaching $P_{1}$, always remains on circle (1), therefore

$$
\begin{equation*}
x_{3}^{3}+y_{3}^{2}=r^{2} ; \quad . \quad . \tag{5}
\end{equation*}
$$

hence, subtracting equation (4) from equation (5).

$$
x_{2}^{2}-x_{1}^{2}+y_{2}^{2}-y_{1}^{2}=0
$$

that is, $\quad\left(y_{2}-y_{1}\right)\left(y_{3}+y_{1}\right)=-\left(x_{3}-x_{1}\right)\left(x_{3}+x_{1}\right)$;
whence,

$$
\frac{y_{2}-y_{1}}{x_{3}-x_{1}}=-\frac{x_{2}+x_{1}}{y_{3}+y_{1}} .
$$

substituting this result in equation (2) gives

$$
\begin{equation*}
y-y_{1}=-\frac{x_{2}+x_{1}}{y_{2}+y_{1}}\left(x-x_{1}\right)_{1} \quad . \tag{6}
\end{equation*}
$$

which is the equation of the secant line LM of the given circle (1).

[^26]Now let $P_{2}$ move along the circle until it coincides with $P_{1}$, i.e., until $x_{2}=x_{1}$, and $y_{2}=y_{1}$, then equation (6) becomes

$$
y-y_{1}=-\frac{x_{1}+x_{1}}{y_{1}+y_{1}}\left(x-x_{1}\right)
$$

i.e.,

$$
y-y_{1}=-\frac{x_{1}}{y_{1}}\left(x-x_{1}\right)
$$

which, by clearing of fractions and transposing, may be written in the form

$$
\begin{array}{ll} 
& x_{1} x+y_{1} y=x_{1}^{2}+y_{1}^{2} \\
\text { i.e., } & x_{1} x+y_{1} y=r^{2} \tag{35}
\end{array}
$$

which is the required equation of the tangent to the circle $x^{2}+y^{2}=r^{2}, x_{1}$ and $y_{1}$ being the coördinates of the point of tangency.
( $\beta$ ) Center of circle not at origin. If the equation of the given circle be

$$
\begin{equation*}
x^{2}+y^{2}+2 G x+2 F y+C=0 \tag{7}
\end{equation*}
$$

then, $P_{1}$ and $P_{2}$ being on this circle,
and

$$
\begin{equation*}
x_{1}^{2}+y_{1}^{2}+2 G x_{1}+2 F y_{1}+C=\dot{v}, \tag{8}
\end{equation*}
$$

$$
\begin{equation*}
x_{2}^{2}+y_{2}^{2}+2 G x_{2}+2 F y_{2}+C=0 . \tag{9}
\end{equation*}
$$

Subtracting equation (8) from equation (9),

$$
x_{2}^{2}-x_{1}^{2}+2 G\left(x_{2}-x_{1}\right)+y_{2}^{2}-y_{1}^{2}+2 F\left(y_{2}-y_{1}\right)=0
$$

which may be written in the form

$$
\left(y_{2}-y_{1}\right)\left(y_{2}+y_{1}+2 F\right)=-\left(x_{2}-x_{1}\right)\left(x_{2}+x_{1}+2 G\right)
$$

whence,

$$
\frac{y_{2}-y_{1}}{x_{2}-x_{1}}=-\frac{x_{2}+x_{1}+2 G}{y_{2}+y_{1}+2 F} .
$$

Substituting this result in equation (2) gives

$$
\begin{equation*}
y-y_{1}=-\frac{x_{2}+x_{1}+2 G}{y_{2}+y_{1}+2 \boldsymbol{b}}\left(x-x_{1}\right) \tag{10}
\end{equation*}
$$

as the equation of the secant through the two points $\left(x_{1}, y_{1}\right)$ and $\left(x_{2}, y_{3}\right)$ on the circle (i). 1f, now, the point $\left(r_{z}, y_{2}\right)$ moves along the curve until it comes into coincidence with $\left(r_{1}, y_{1}\right)$, this secant line becomes a tangent, and its equation is

$$
\begin{equation*}
y-y_{1}=-\frac{x_{1}+G}{y_{1}+F}\left(x-x_{1}\right) \tag{11}
\end{equation*}
$$

Clearing equation (11) of fractions, and transposing, it may be written thus:

$$
x_{1} x+y_{1} y+G x+F y=x_{1}^{2}+y_{1}^{2}+G x_{1}+F_{y_{1}} ; \ldots(12)
$$

bitt, by equation (8), the second member of equation (12) equals

$$
-G x_{1}-F_{y_{1}}-C
$$

Putting this value for the second member in equation (12), dul transposing, that equation becomes

$$
x_{1} x+y_{1} y+G\left(x+x_{1}\right)+F\left(y+y_{1}\right)+C=0, \ldots[36]
$$

which is the required equation of the tangent to the circle (i), $x_{1}$ and $y_{1}$ being the coordinates of the point of contact.*

Xutk. Equation [30] may be easily remembered if it be olserved that it differs from the equation of the circle [equation ( 7 )] only in having $x_{1} x_{1} y_{1} y, x+x_{1}$, and $y+y_{1}$ in place of $x^{2}, y^{2}, 2 x_{1}$, and $2 y$, respectipely. It will be found later that any equation of the seceond degree (from which the ry-term is ahsont) bears this same relation to the equaHen of a tangent to its locus, $x_{1}$ and $y_{1}$ being the coordinates of the point of contact. Compare, also, equation [35] with equation (1).

It must also be carefully kept in mind that equations [35] and [338] mprement tangents only if $\left(x_{1}, y_{1}\right)$ is a point on the circle. It will lee seen Inter that these equations represent other lines if $\left(x_{y}, y_{1}\right)$ is not on the circle.
85. Equation of a normal to a given circle. By definition (Art. 81) the normal at a given point, $P_{1} \equiv\left(x_{1}, y_{1}\right)$, on any

[^27]curve is the line through $P_{1}$, and perpendicular to the tangent at $P_{1}$. Hence, to get the equation of the normal at any given point, it is only necessary to write the equation of the tangent at this point (Art. 84), and then the equation of a line perpendicular to this tangent (Arts. 53, 62) and passing through the given point. Thus the equation of the normal to the circle
\[

$$
\begin{equation*}
x^{2}+y^{2}+2 G x+2 F y+C=0 \tag{1}
\end{equation*}
$$

\]

at the point $P_{1} \equiv\left(x_{1}, y_{1}\right)$, is

$$
\begin{equation*}
y-y_{1}=\frac{y_{1}+F}{x_{1}+G}\left(x-x_{1}\right) \tag{2}
\end{equation*}
$$

The coördinates $-G$ and $-F$ of the center of the given circle (1) satisfy equation (2); hence, every normal to a circle passes through the center of the circle.

If the center of the circle be at the origin, then $G=0$, $F=0$, and $C=-r^{2}$, and the equation (2) of the normal becomes

$$
\begin{equation*}
y-y_{1}=\frac{y_{1}}{x_{1}}\left(x-x_{1}\right) \tag{3}
\end{equation*}
$$

which reduces to $x_{1} y-x y_{1}=0$, - an equation which could have been derived for the circle $x^{2}+y^{2}=r^{2}$ in precisely the same way that equation (2) was derived from equation (1).

## EXERCISES

1. Derive, by the secant method, the equation of the tangent to the circle $x^{2}+y^{2}=2 r x$, the point of contact being $P_{1} \equiv\left(x_{1}, y_{1}\right)$.
2. Write the equation of the tangent to the circle:
(a) $x^{2}+y^{2}=25$, the point of contact being $(3,4)$;
( $\beta$ ) $x^{2}+y^{2}-3 x+10 y=15$, the point of contact being $(4,-11)$;
(y) $(x-2)^{2}+(y-3)^{2}=10$, the point of contact being (5,4);
( $\delta) 3 x^{2}+3 y^{2}-2 y-4 x=0$, the point of contact being $(0,0)$.
3. Find the equation of the sommal to each of the circles of Ex. 2, thraugh the given point.
4. A tangent is perpendienlar to the rodius drawn to ite peoint of conitart By means of this fact, derive the equation of the tangent to the circle $(x-a)^{2}+(g-b)^{3}=r^{2}$ at the point $\left(r_{v}, y_{1}\right)$ (ef. equation [ab])
5. From the fact thint a normal to a circle passes through its certeor, final the equation of the normal to the circle $x^{2}+y^{4}-6 x+5 y+21=0$ at the point $(1,-4)$.
6. Find the equations of the two tangente, drawn through the ex. ternal point $(11,3)$ to the circle $x^{2}+y^{2}=30$.

Scigestios. The the equation of the tangent in terms of its slope
7. What is the equation of the circle whose center is at the proint ( 5,3 ), and which touches the line $3 x+2 y-10=0$ ?
8. Under what condition will the line $\frac{x}{a}+\frac{y}{b}=1$ touch the circle $x^{3}+y^{3}=r^{3}$ ?
9. Find the equation of a circle inscribed in the triangle whose sides are the lines $x=0, y=0$, and $\frac{x}{a}+\frac{y}{b}=1$.
10. Solve Ex. 6 by assuming $x_{1}$ and $y_{1}$ as the coorrdinates of the point of contact, and then finding their mumerical values from the two equations which they satisfy.
86. Lengths of tangents and normals. Subtangents and subnormals. The tangent and normal lines of any curve extend indefinitely in both directions ; it is, however. convenient to consider as the length of the tangent the lougth $T P_{1}$, measured from the point of intersection ( $T$ ) of the tangent with the $x$ axis to the point of tangency
 $\left(P_{1}\right)$, and similarly to consider as the length of the normal the length $P_{1}, V$, measured from $P_{1}$ to the point of intensection $(N)$ of the normal with the $x$-axis.

The subtangent is the length $T M$, where $M$ is the foot of the ordinate of the point of tangency $P_{1}$; and the subnormal is the corresponding length $M N$. As thus taken, the subtangent and the subnormal are of the same sign ; ordinarily, however, one is concerned merely with their absolute values, irrespective of the algebraic sign. The subtangent is the projection of the tangent length on the $x$-axis, and the subnormal is the like projection of the normal length.
87. Tangent and normal lengths, subtangent and subnormal, for the circle. The definitions given in the preceding article furnish a direct method for finding the tangent and normal lengths, as well as the subtangent and subnormal, for a circle. E.g., to find these values for the circle $x^{2}+y^{2}=25$, and correspond-
 ing to the point of contact $(3,4)$, proceed thus:

The equation of the tangent $P_{1} T$ is (Art. 84)

$$
3 x+4 y=25
$$

hence the $x$-intercept of this tangent, i.e., OT, $=\frac{25}{8}$; therefore the subtangent $T M$, which equals $O M-O T$, is $3-\frac{25}{3}$, i.e., $-5 \frac{1}{3}$. The tangent length

$$
T P_{1}=\sqrt{M T^{2}+\overline{M P_{1}^{2}}}=\sqrt{\left(\frac{16}{3}\right)^{2}+4^{2}}=6 \frac{2}{3}
$$

To find the normal length, and the subnormal, first write the equation of the normal at the point $(3,4)$; it is (Art. 85) $4 x-3 y=0$. Hence its $x$-intercept is zero, and the subnormal, $M O$ in this case, is -3 ; the normal length $P_{1} O$ is 5 .

Similarly, corresponting to the puint $\left(x_{1}, y_{1}\right)$ an the circle $x^{3}+y^{2}=r^{3}$, the subtangent $=-\frac{y_{1}{ }^{2}}{x_{1}}$, the tangent length $=\frac{r y_{1}}{x_{1}}$, the subnormal $=-x_{1}$, and the normal length $=r$. The derivation of these values is left as an exercise for the student, as is also the derivation of the corresponding espressions for the circle $x^{3}+y^{2}+2 G x+2 F y+C=0$, the point of contace being $\left(x_{1}, y_{1}\right)$.

## EXERCISES

Find the lengths of the tangent, subtangent, normal, and submormal,

1. for the pwint $(4,-11)$ on the circle $x^{2}+y^{2}-3 z+10 y=15$;
2. for the point $(1,3)$ on the circle $x^{2}+y^{3}-10 x=0$;
3. For the point whose abscissa is $\sqrt{7}$ on the circle $x^{2}+y^{2}=25$.
4. The subtangent for a certain point on a circle, whose center is at the origin, is $5 j$, and its subnormal is 3 . Find the equation of the circle, and the point of tangency.
5. To find the length of a tangent from a given external point to a given circle. Let $P_{1} \equiv\left(x_{1}, y_{1}\right)$ be the given external point, and let

$$
x^{2}+y^{2}+2 G x+2 F y+C=0
$$

be the given circle. The center of this circle (Art. 79) is $(-G,-F)$, and its radius is $\sqrt{\sigma^{2}+F^{2}-C}$. Join $P_{1}$ to the center $K$, draw the tangent $P_{1} Q$, and also the radius $K Q$. Then $\overline{P_{1} V^{2}}=\overline{K P_{1}^{2}}-K Q^{2}$; but

$$
\bar{h}_{1}^{2}=\left(x_{1}+F^{2}+\left(y_{1}+F\right)^{2}\right.
$$

 (Art. 26)
and

$$
\begin{equation*}
\overline{K v^{2}}=G^{2}+F^{2}-C ; \tag{Art.79}
\end{equation*}
$$

$$
\begin{aligned}
\therefore \quad \overline{P_{1} Q^{2}} & =\left(x_{1}+G\right)^{2}+\left(y_{1}+F\right)^{2}-\left(G^{2}+F^{2}-C^{\prime}\right) \\
& =x_{1}^{2}+y_{1}^{2}+2 G x_{1}+2 F y_{1}+C,
\end{aligned}
$$

i.e., the square of the length of the tangent from a given external point to the circle $x^{2}+y^{2}+2 G x+2 F y+C=0$ * is obtained by writing the first member only of this equation, and substituting in it the coördinates of the given point. $\dagger$
89. From any point outside of a circle two tangents to the circle can be drawn. (a) Let the equation of the circle be

$$
\begin{equation*}
x^{2}+y^{2}=r^{2}, \quad . \quad . \tag{1}
\end{equation*}
$$

then (Art. 83) the line

$$
\begin{equation*}
y=m x+r \sqrt{1+m^{2}} \tag{2}
\end{equation*}
$$

is, for all values of $m$, tangent to this circle. Let $P_{1} \equiv\left(x_{1}, y_{1}\right)$ be any given point outside the circle (1); then the tangent (2) will pass through $P_{1}$ if, and only if, $m$ be given a value such that the equation
shall be satisfied.

$$
\begin{equation*}
y_{1}=m x_{1}+r \sqrt{1+m^{2}} \tag{3}
\end{equation*}
$$

Transposing, squaring, and rearranging equation (3), it is clear that it will be satisfied if, and only if, $m$ is given a value such that the equation

$$
\left(r^{2}-x_{1}^{2}\right) m^{2}+2 x_{1} y_{1} m+r^{2}-y_{1}^{2}=0
$$

is satisfied; i.e., equation (3) is satisfied if, and only if,

$$
\begin{equation*}
m=\frac{-x_{1} y_{1} \pm r \sqrt{x_{1}^{2}+y_{1}^{2}-r^{2}}}{r^{2}-x_{1}^{2}} \tag{4}
\end{equation*}
$$

Equation (4) gives two, and only two, real values for $m$ when $\left(x_{1}, y_{1}\right)$ is outside of the circle, for then $x_{1}^{2}+y_{1}^{2}-r^{2}$ is

[^28]prositive (Art. 78, foot-nute) ; these values of $m$, being substituted in turn in equation ( $\mathrm{Z}^{2}$ ), give the two tangents through $P_{1}$ to the circle (1).

If $P_{1}$ is on the circle ( 1 ), then $x_{1}^{2}+y_{1}^{2}-r^{3}=0$; bence the two values of $m$ from equation ( $t$ ) coincide, and the two tangents also coincide, i.e., there is in this case but one tangent. If $P_{1}$ is within the circle, then the two values of $m$ from equation (4) are both imaginary and no tangent through $P_{1}$ can be drawn to the circle (1). ${ }^{*}$

If either value of $m$ from equation ( 4 ) is substituted in equation (2), and then equations (2) and (1) are considered as simultaneons and solved for $x$ and $y$, the courdinates of the corresponding point of contact are obtained.

Sors. The properties of the equations of the line and circle have thus cotabhished a geometrie property of the circle [cf. Art. 31, (III)].
(8) If the equation of the given circle had been

$$
\begin{equation*}
x^{2}+y^{2}+2 G x+2 F y+C=0 \tag{5}
\end{equation*}
$$

it could, by Art. 71, have been transformed to new axes through its center ( $-\boldsymbol{G},-\boldsymbol{F}$ ) and parallel respectively to the giren axes; its equation would thus have become

$$
\begin{equation*}
x^{2}+y^{\prime 2}=r^{3} \tag{6}
\end{equation*}
$$

where $x^{\prime}$ and $y^{\prime}$ refer to the new axes.
This transformation, however, leaves the circle and all its intrinsic properties unchanged; but (a) applies to circle (6). hence it is proved that circle (5), which is circle (6) merely referred to other axes, has the same properties.

[^29]90. Chord of contact. If two tangents are drawn from any external point to a circle, the line joining the two corresponding points of tangency is called the chord of contact for the proint from which the tangents are drawn.

The equation of this chord of contact may be found by first finding the points of tan-
 gency and then writing the equation of the straight line through those two points. It may, however, be found more briefly, and much more elegantly, as follows:

Let $P_{1} \equiv\left(x_{1}, y_{1}\right)$ be the given external point from which the two tangents are drawn ; and let $T_{2} \equiv\left(x_{2}, y_{2}\right)$ and $T_{8} \equiv\left(x_{8}, y_{8}\right)$ be the points of tangency on the circle

$$
\begin{equation*}
x^{2}+y^{2}+2 G x+2 F y+C=0 \tag{1}
\end{equation*}
$$

it is required to find the equation of the line passing through $T_{2}$ and $T_{3}$. The equation of the tangent at $T_{2}$ is (Art. 84)

$$
x_{2} x+y_{2} y+G\left(x+x_{2}\right)+F\left(y+y_{2}\right)+C=0, \ldots \text { (2) }
$$

and the equation of the tangent at $T_{3}$ is

$$
\begin{equation*}
x_{3} x+y_{3} y+G\left(x+x_{3}\right)+F\left(y+y_{3}\right)+C=0 . \tag{3}
\end{equation*}
$$

But each of these tangents passes through the point $P_{1}$; hence its coördinates, $x_{1}$ and $y_{1}$, satisfy equations (2) and (3), therefore

$$
\begin{equation*}
x_{1} x_{2}+y_{1} y_{2}+G\left(x_{1}+x_{2}\right)+\boldsymbol{F}\left(y_{1}+y_{2}\right)+C=0, \ldots \tag{4}
\end{equation*}
$$

and $\quad x_{1} x_{3}+y_{1} y_{3}+G\left(x_{1}+x_{3}\right)+F\left(y_{1}+y_{3}\right)+C=0 \ldots$.
Equations (4) and (5), however, assert respectively that $\left(x_{2}, y_{2}\right)$ and $\left(x_{3}, y_{3}\right)$ are points on the locus of the equation

$$
\begin{equation*}
x_{1} x+y_{1} y+\boldsymbol{G}\left(x_{1}+x\right)+\boldsymbol{F}\left(y_{1}+y\right)+C=0 \ldots \tag{6}
\end{equation*}
$$

But equation (6) is of the first degree in the two variables $x$ and $y$, hence (Art. 57 ) its locus is a straight line, and, since it passes through both $T_{3} \equiv\left(x_{y}, y_{2}\right)$ and $T_{0} \equiv\left(x_{3}, y_{1}\right)$, it is the equation of the chord of contact ;
i.e., $x_{1} x+y_{1} y+G\left(x+x_{1}\right)+F\left(y+y_{1}\right)+C=0$... [37]
is the equation of the chord of contact corresponding to the esternal point $P_{1} \equiv\left(x_{1}, y_{1}\right)$.
It is to be noticed that if $P_{1}$ is on the circle, then the two tangents drawn through it coincide with each other and with the chord of contact; the equation of the chord of contact [37] then becomes the equation of the tangent at $P_{1}$, as it should (ef. equation [36]).

If, then, $\left(x_{1}, y_{1}\right)$ is a point on the circle (1), equation [37] is the equation of the tangent to the circle at that point; if, on the other hand, $\left(x_{1}, y_{1}\right)$ is outside of this circle, then equation [37] is not the equation of a tangent, but of the chord of contact corresponding to that external point.

## EXERCISES

1. Find the length of the tangent from the point $(8,10)$ to the circles:
(a) $x^{2}+y^{2}-3 x=0$;
( $\beta$ ) $2 x^{2}+2 y^{2}=5 y+6$.
2. (a) Write the equation of the chord of contact corresponding to the point ( 5,6 ) for the circle $x^{2}+y^{3}-6 x-4 y=1$.
( $\beta$ ) Find the coordinates of the points in which this chord euts the circle.
(y) Write the equations of the tangents to the circle at these points of intersection; show that these lines pass throngh the given point ( 5,6 ).
3. By tho method of exercise 2, find the equations of the tangents drawa to the circle $(3 x-2)^{2}+(3 y+5)^{2}=4$, from the origin; from the point (1, 2).
4. Find the locus of a proint from which the tangents drawn to the two circles

$$
2 x^{2}+2 y^{2}-10 x+14 y+3.5=0 \text { and } x^{3}+y^{3}=0
$$

are of equal length. Show that this loeus is a straight line perpendicular the line joining the centers of the given circles.
5. For what point is the line $3 x+4 y=7$ the chord of contact with regard to the circle $x^{2}+y^{3}=14$ ?
6. Find the chorid of contact for the circle $x^{2}+y^{2}=25$, corresponding to the point $(3,7)$; to the print $(3,2)$.
7. By means of the equation $y-y_{1}=m\left(x-x_{1}\right)$ prove that two tangents can be drawn through the external point $\left(x_{1}, y_{1}\right)$ to the circle whose equation is $x^{2}+y^{2}=r^{2}$.
8. Solve $(\beta)$ and $(\gamma)$, of exercise 2, by means of the equation

$$
y-6=m(x-5)
$$

91. Poles and Polars. If through any given point: $P_{1} \equiv\left(x_{1}, y_{1}\right)$, outside, inside, or on the circle, a secant is drawn, meeting the circle in two
 points, as $Q$ and $R$, and if tangents are drawn at $Q$ and $R$, they will intersect in some point as

$$
P^{\prime} \equiv\left(x^{\prime}, y^{\prime}\right)
$$

The locus of $P^{\prime}$, as the secant revolves about $P_{1}$, is called the polar of $P_{1}$ with regard to the circle; and $\boldsymbol{P}_{1}$ is the pole of that locus. It will be proved in the next article that the locus of $P^{\prime}$ is a straight line whose equation is of the same form as that of the tangent (Art. 8t), and as that of the chord of contact (Art. 90) already found.
92. Equation of the polar. Let $P_{1} \equiv\left(x_{1}, y_{1}\right)$ be the given point, the equation of whose polar, with regard to the circle

$$
\begin{equation*}
x^{2}+y^{2}+2 G x+2 F y+C=0 \tag{1}
\end{equation*}
$$

is sought. Also let $P_{1} Q R$ be any position of the secant through $P_{1}$, and let the tangents at $Q$ and $R$ intersect in $P^{\prime} \equiv\left(x^{\prime}, y^{\prime}\right)$; then the equation of $P_{1} Q R$ (Art. 90) is

$$
\begin{equation*}
x^{\prime} x+y^{\prime} y+G\left(x+x^{\prime}\right)+\boldsymbol{F}\left(y+y^{\prime}\right)+C=0 \tag{2}
\end{equation*}
$$

Since $P_{1}$ is on this line, therefore

$$
x_{1} x^{\prime}+y_{1} y^{\prime}+G\left(x_{1}+x^{\prime}\right)+F\left(y_{1}+y^{\prime}\right)+C=0 \ldots(B)
$$

Equation (3) asserts that the coobrdinates, $x^{\prime}$ and $y^{\prime}$, of $P^{3}$ satiafy the equation

$$
x_{1} x+y_{1} y+G\left(x+x_{1}\right)+\boldsymbol{F}\left(y+y_{1}\right)+C=0 ; \ldots[38]
$$

i.e., this variable point $P^{M}$ always lies on the locus of equation [88]; in other words, [38] is the equation of the polar of $P_{1}$ with regard to the circle (1).

Moreover, since equation [38] is of the first degree in the variables $x$ and $y$, therefore (Art. 5i) its locus is a straight line: that is, the polar of any given point, with regard to any gieen circle, is a straight line.

That equations [3i] and [37] have the same form as equation [38] is due to the fact that the tangent and the chord of contact are only special cases of the polar.
93. Fundamental theorem. An important theorem concerning poles and polars is: If the polar of the point $P_{1}$. with regard to a given eircle. pasacs through the point $P_{2}$, thom the polar of $P_{3}$ passes through $P_{1}$. Let the equation of the given circle be

$$
\begin{align*}
& x^{2}+y^{2}+2 G x+2 F y \\
& \quad+C=0, \tag{1}
\end{align*}
$$

and let the two given points
be $\quad P_{1} \equiv\left(x_{1}, y_{1}\right)$,
and $P_{2} \equiv\left(x_{2}, y_{2}\right)$;

then (Art. 92) the equation of the polar of $P_{1}$ is

$$
\begin{equation*}
x_{1} x+y_{1} y+G\left(x+x_{1}\right)+\boldsymbol{F}\left(y+y_{1}\right)+\boldsymbol{C}=0 . \tag{2}
\end{equation*}
$$

If this line passes through $P_{2}$, then

$$
x_{1} x_{2}+y_{1} y_{2}+G\left(x_{2}+x_{1}\right)+F\left(y_{2}+y_{1}\right)+C=0 \ldots \text { ( } . .
$$

But the equation of the polar of $P_{3}$ (Art. 92 ) is

$$
\begin{equation*}
x_{2} x+y_{2} y+G\left(x+x_{2}\right)+F\left(y+y_{2}\right)+C=0, \ldots \tag{4}
\end{equation*}
$$

and equation (3) proves that the locus of equation (1) passes through $P_{1}$, which establishes the theorem.

## EXERCISES

1. Find the polar of the point $(6,8)$ with reference to the circle $x^{2}+y^{2}=14$.
2. Find the polar of the point $(1,2)$ with regard to the circle $x^{2}+y^{2}+4 x-6 y=10$.
3. Find the pole of the line $4 x+6 y=7$, and of the line $a x+b y-1=0$, with regard to the circle $x^{3}+y^{8}=35$.
4. Find the equations of the two tangents to the circle $x^{2}+y^{2}=05$ from the point $(4,7)$; from the point $(11,3)$.
5. Show that if the polar of $(h, k)$ with respect to the circle $x^{2}+y^{2}=c^{2}$ touch the circle $4\left(x^{2}+y^{2}\right)=c^{2}$, then the pole ( $h, k$ ) will lie on the circle $x^{2}+y^{2}=4 c^{2}$.
6. Show that the pole of the line joining $(5,7)$ and $(-11,1)$ is the point of intersection of the polars of those two points with reference to the circle $x^{2}+y^{2}=100$.
7. Find the pole of the line $2 x-3 y=0$ with respect to the circle $x^{2}+y^{2}=9$.
8. Show what specialization of a polar converts it into a chord of contact, and what further specialization converts it into a tangent.
9. Geometrical construction for the polar of a given point, and for the pole of a given line, with regard to a given circle. Since the relation between a polar and its pole (see def. Art. 91) is independent of the coördinate axes, therefore the given circle may, without loss of generality, be assumed to have its center at the origin.

If $P_{1} \equiv\left(x_{1}, y_{1}\right)$ is any given point, and

$$
\begin{equation*}
x^{2}+y^{2}=r^{2} \tag{1}
\end{equation*}
$$

is a given circle, whose center is at the proint $O$, thess the equation of $O P_{1}$ (Art. 51) is

Let $L L_{1}$ be the polar of $P_{1}$, with regard to the given circle, and let it meet $O P_{1}$ in $K$. The equation of $L L_{1}$ (Art. 92) is

$$
\begin{equation*}
x_{1} x+y_{1} y=r^{2} \tag{8}
\end{equation*}
$$

Equations (2) and (3) show (Art. 62) that $L L_{1}$ and $O P_{1}$ are perpendicular to each other; i.e., the line joining the given point $P_{1}$ to the center of the circle is perpendicular to the polar of $P_{1}$ with regard to the circle.
The distance ( $O K$ ) from the origin to the line $L L_{1}$ (Art. B4) is

$$
\begin{equation*}
\frac{r^{2}}{\sqrt{x_{1}^{2}+y_{1}^{2}}} \tag{4}
\end{equation*}
$$

and the length of $O P_{1}$ (Art. 26) is

$$
\begin{equation*}
\sqrt{x_{1}^{2}+y_{1}^{2}} ; \tag{5}
\end{equation*}
$$

therefore

$$
O K \cdot O P_{1}=\frac{r^{2}}{\sqrt{x_{1}^{2}+y_{1}^{2}}} \cdot \sqrt{x_{1}^{2}+y_{1}^{2}}=r^{2} .
$$

Hence, to construct, with regard to a given circle, the polar of any given point $P_{1}$, join that point to the center of the circle. then on $O P_{1}$ (produced if necessary) find a proint $K$ such that the rectangle $O P_{1} \cdot O K$ is equal to the square
on the radius of the circle, and through $K$ draw a line perpendicular to $O P_{1}$; this line is the required polar.

Similarly the pole may be constructed, if the polar and the circle are given.
95. Circles through the intersections of two given circles. Given two circles whose equations are
and

$$
\begin{equation*}
x^{2}+y^{2}+2 G_{1} x+2 F_{1} y+C_{1}=0 \tag{1}
\end{equation*}
$$

These circles intersect, in general, in two finite points $P_{1} \equiv\left(x_{1}, y_{1}\right)$ and $P_{2} \equiv\left(x_{2}, y_{2}\right)$, and (Art. 41) the equation $x^{2}+y^{2}+2 G_{1} x+2 F_{1} y+C_{1}$

$$
\begin{equation*}
+k\left(x^{2}+y^{2}+2 G_{2} x+2 F_{2} y+C_{2}\right)=0 \tag{3}
\end{equation*}
$$

where $k$ is any constant, represents a curve which passes through these same points $P_{1}$ and $P_{2}$.

The locus of equation (3) is, moreover, a circle (Art. 79); hence, a series of different values being assigned to the parameter $k$, equation (3) represents what is called a "family" of circles; each one of these circles passing through the two points $P_{1}$ and $P_{2}$ in which the given circles (1) and (2) intersect each other.
96. Common chord of two circles. If in equation (3), Art. 95 , the parameter $k$ be given the particular value -1 , the equation reduces to

$$
\begin{equation*}
2\left(G_{1}-G_{2}\right) x+2\left(F_{1}-F_{2}\right) y+C_{1}-C_{2}=0 \tag{4}
\end{equation*}
$$

which is of the first degree, and therefore represents a straight line; but this locus belongs to the family represented by equation (3) of Art. 95, hence it passes through the two points $P_{1}$ and $P_{2}$ in which the circles (1) and (2) intersect. This line (4) is, therefore, the common chord * of these circles.

To obtain the equation of the common chard of tro gives cincten it is Hom, only nepemsary to eliminate the terms in $x^{3}$ and $y^{3}$ between their equations. E. $g$, to find the common chord of the circtes

$$
\begin{align*}
& 2 x^{2}+2 y^{2}+3 x+5 y-9=0  \tag{a}\\
& 6 x^{2}+6 y^{2}+11 x+13 y-23=0
\end{align*}
$$

and
uultiply equation (a) loy 3 and subtract the result from equation (/B): this gives

$$
x-y+2=0
$$

as the equation of the common chord of the given circles.
This result may be verified by finding the points of intarsection ( $1 r$. 39 ) of the circles ( $\alpha$ ) and $(\beta)$, and then writing the equation of the straight line through thase two points.

Since the common chord of two circles internects each of these circles in the pminta in which they intersect each other, therefore the points of intersection of two circles may be found by finding the puints in which their common chord interseets either of them. E.g., to find the points in which the circles (a) and ( $\beta$ ) intersect each other, it is only necmary to find the grints in which $(\gamma)$ cuts either $(a)$ or $(\beta)$.
97. Radical axis ; radical center. The line whose equation is obtained by eliminating the $x^{3}$ and $y^{2}$ terms between the equations of two given circles, as in Art. 96, whether the circles intersect in real points or not, is called the radical axis of the two circles. If the two given circles intersect each other in real points, then this line is also called their common chord ; that is, the common chord of two circles is a special ease of the radieal axis of two circles.

- Equation (3) of Art. 95 , which for every value of \& sppresentas a circle pesing through the two points in which the given circles (1) and (2) intermet, may be writuen in the form

$$
x^{2}+y^{3}+2 \frac{G_{1}+k F_{2}}{1+k}+2 \frac{F_{1}+k F_{3}}{1+k} y+\frac{C_{1}+k C_{3}}{1+k}=0 .
$$

The colirdinates of the center of this circle are (Art. 50)

$$
-\frac{a_{1}+k G_{3}}{1+k} \text { and }-\frac{F_{1}+k F_{3}}{1+k}
$$

If chen $k$ be made to approach -1 , beth of these coördinates appmach infinity, but the circle always panses through the two fixed proints in which the given rimeles intersert; hence the combuns chand of two given circles thay be ryganded as an infinitely large circle whose center is at infinity.

Three circles, taken two and two, have three radical axes. It is easily shown that these three radical axes pass through a common point ; this point is called the radical center of the three circles.

## EXERCISES

1. Find the equation of the common chord of the circles

$$
x^{2}+y^{2}-3 x-5 y-8=0, x^{2}+y^{2}+8 x=0
$$

2. Find the points of intersection of the circles in exercise 1 , and the length of their common chord.
3. Find the radical axis, and also the length of the common chord, for the circles $x^{2}+y^{2}+a x+b y+c=0, x^{2}+y^{2}+b x+a y+c=0$.
4. Find the radical center of the three circles

$$
\begin{gathered}
x^{2}+y^{2}+4 x+7=0, \\
2\left(x^{2}+y^{2}\right)+3 x+5 y+9=0, \\
x^{2}+y^{2}+y=0 .
\end{gathered}
$$

5. Show that tangents from the radical center, in exercise 4 , to the three circles, respectively, are equal in length.
6. Prove analytically that the tangents to two circles from any point on their radical axis are equal.
7. Find the polar of the radical center of the circles in exercise 4, with respect to each circle.
8. Prove analytically that the three radical axes of three circles, the circles being taken in pairs, meet in a common point.
9. The equation of a circle : polar coördinates. Let $O R$ be the initial line, $O$ the pole, $C \equiv\left(\rho_{1}, \theta_{1}\right)$ the center of the circle, $r$ its radius, and $P \equiv(\rho, \theta)$
 any point on the circle. Draw $O C$, $O P$, and $O P$; then, by trigonometry.

$$
\begin{aligned}
& r^{2}=\rho^{2}+\rho_{1}{ }^{2}-2 \rho \rho_{1} \cos \left(\theta-\theta_{1}\right), \text { i.e., } \\
& \rho^{2}-2 \rho_{1} \rho \cos \left(\theta-\theta_{1}\right) \\
& \quad+\rho_{1}^{2}-r^{2}=0, \ldots[39]
\end{aligned}
$$

which is the equation of the given circle.

Depending upon the relative positions of the polar asis, the pole, and the center of the circle, equation [89] has several special forms:
(a) If the eenter is on the polar axis, then $\theta_{1}=0$, and equation [89] becomes

$$
\rho^{2}-2 \rho_{1} \rho \cos \theta+\rho_{1}^{2}-r^{2}=0 ;
$$

( $\beta$ ) If the pole is on the circle, then $\rho_{1}=r$, and equation [39] becomes

$$
\rho-2 r \cos \left(\theta-\theta_{1}\right)=0
$$

(y) If the pole is on the circle and the polar axis a diamewer, then $\rho_{1}=r$ and $\theta_{1}=0$, and equation [39] becomes

$$
\rho-2 r \cos \theta=0
$$

( $\delta$ ) If the center is at the pole, then $\rho_{1}=0$ and equation [89] becomes

$$
\rho=r
$$

99. Equation of a circle referred to oblique axes. Lett the aves $O X$ and $O Y$ be inclined at an angle $\omega$; let $C \equiv(h, k)$ he the center of the circle, $r$ its radius, and $P \equiv(x, y)$ any print on the circle. Draw the nrdinates $M_{1} C$ and $M P$, connect $G$ and $P$, and draw CHL parallef to the $x$-axis ; then

$$
\begin{aligned}
C P^{2} & =C H^{2}+H P^{3} \\
& +2 C H \cdot H P \cos \omega
\end{aligned}
$$

Fas.
hence $r^{2}=(x-h)^{2}+(y-k)^{2}+2(r-h)(y-k) \cos \omega$. i.e., $(x-h)^{2}+(y-k)^{2}+2(x-h)(y-k) \cos \omega-r^{2}=0 ; \ldots[40]$ which is the equation of the given circle.

It is to be observed that this equation [40] is not of the form

$$
x^{2}+y^{2}+2 G x+2 F y+C=0
$$

which was discussed in Art. 79 ; it differs from that equation in that it contains an $x y$-term. If, however, the axes are rectangular, as in Art. 79, then $\cos \omega=0$, and equation [40] reduces to the standard form of Art. 79, viz.:

$$
x^{2}+y^{2}+2 G x+2 F y+C=0
$$

which is a special case of equation [40].
100. The angle formed by two intersecting curves. By the angle between two intersecting curves is meant the angle formed by the two tangents, one to each curve, drawn through the point of intersection.

Hence to find the angle at which two curves intersect, it is only necessary to find the point of intersection, then to fiad the equations of the tangents at this point, one to each curve, and finally to find the angle formed by these tangents.

## EXERCISES

1. Find the polar equation of the circle whose center is at the point $\left(7, \frac{\pi}{4}\right)$ and whose radius is 10 ; determine also the points of its intersection with the initial line.
2. Find the polar equation of a circle whose center is at the point ( $15, \frac{\pi}{2}$ ) and whose radius is 10 . Find also the equations of the tangents to the circle from the pole.
3. A circle of radius 3 is tangent to the two radii vectores which make the angles $60^{\circ}$ and $120^{\circ}$ with the initial line: find its polar equation, and the distance of the center from the origin.
4. Find the equation of a circle of radius 5 , with center at the point $(2,3)$, if $\omega$ is $60^{\circ}$.
5. Find the equation of a circle of radius 2 , with center at the origin, if $\omega$ is $120^{\circ}$.
6. Intarmine the equation of the circle circumseriling ass equilatoral trtangle, - the corordiwate axes being two ables of the triangle.
7. A circle is inseribed in a mpuare. What is its equation, if a sisle ant adjacent diagomal of the spuare are chosen as the $y$ and as-asis. rexpectirely? What are the countinates of the points of tangeney?
8. Find the augle at which the circle $x^{3}+y^{3}=0$ jutarnecte the circle $(e-4)^{2}+y^{2}-2 y=15$. At what angle dues the second of these circles moet the line $x+2 y=4$ ?

## EXAMPLES ON CHAPTER VII

1. Find the eqguations of the circle circumscribing the triangle whome vertices are at the points $(7,2),(-1,-4)$, and $(3,3)$. What is its conter? ite radius?
2. Determine the center of the circle

$$
(x+a)^{2}+(y+b)^{2}=a^{2}+b^{2}
$$

What family of circles is represented by this equation, if $a$ and $b$ vary under the one restriction that $a^{2}+b^{3}$ is to remain constant?
3. What must be the relations among the coefficients in order that the circles
and

$$
x^{3}+y^{2}+2 G_{1} x+2 F_{1} y+C_{1}=0
$$

shall be concentric? that they shall have equal areas?
4. Linder what limitations upon the coefficients is the circle

$$
A x^{2}+A y^{2}+D x+E y+F=0
$$

tangent to each of the axes?
5. Find the equation of the circle which has ita center on the $x$-axis, and which passes throught the origin and also through the foint $(2,3)$.
6. Find the proints of intersection of the two circles

$$
x^{2}+y^{2}-4 x-2 y-31=0 \text { and } x^{2}+y^{2}-4 x+2 y+1=0
$$

7. Circles are drawn having their conters at the vertices of the triangle ( 7,2 ), $(-1,-4)$ and $(3,3)$, respectively, and each paseing through the center of a fourth circle which circumecribes this triangle; find their apuations, their common chorils, and their radieal center.
8. Circles having the sidles of the triangle $(7,2),(-1,-4),(3,3) \mathrm{ms}$ dianmers are drawn; find their equations, their radical axes, and their radical conter.
9. Find the equation of the circle passing through the origin and the point $\left(x_{1}, y_{3}\right)$, and having its center on the $y$-axis.
10. The point $(3,-5)$ lisects a chord of the circle $x^{2}+y^{2}=277$; find the equation of that chord.
11. A circle touches the line $4 x+2 y+5=0$ at the point $(-3,3)$ and passes through the point $(5,9)$; find its equation.
12. A circle, whose center coincides with the origin, touches the line $7 x-11 y+2=0$; find ats equation.
13. At the points in which the circle $x^{2}+y^{2}-a x-l y=0$ cuts the axes, tangents are drawn: find the equatious of these tangents.
14. A circle, whose radius is $\sqrt{74}$, touches the line $5 y=7 x-1$ at the point ( 8,11 ) ; find the equ:tion of this circle.
15. A circle is inscribed in the triangle (3, -2), $(3,3),(3,3)$; find its equation; find also the equations of the polars of the three vertices with regard to this circle.
16. Through a fixed point $\left(x_{1}, y_{1}\right)$ a secant line is drawn to the circle $x^{2}+y^{2}=r^{2}$; find the locus of the middle point of the chord which the circle cuts from this secant line, as the secant revolves about the given fised point ( $x_{1}, y_{1}$ ).
17. Prove analytically that an angle inscribed in a semicircle is a right angle.
18. Prove analytically that a radius drawn perpendicular to a chord of a circle bisects that chord.
19. Show that the distances of two points from the center of a circle are proportional to the distances of each from the polar of the other.
20. Two straight lines touch the circle $x^{2}+y^{2}-5 x-3 y+6=0$, one at the point $(1,1)$ and the other at the point $(2,3)$; find the pole of the chord of contact of these tangents.
21. Find he condition among the coefficients that must be satisfied if the circles

$$
x^{2}+y^{2}+2 G_{1} x+2 F_{1} y=0 \text { and } x^{2}+y^{2}+2 G_{2} x+2 F_{2} y=0
$$

shall touch each other at the origin.
22. Determine $F$ and $C$ so that the circle

$$
x^{2}+y^{2}+20 x+2 F y+C=0
$$

shall cut each of the circles

$$
x^{2}+y^{2}-4 x-2 y+4=0 \text { and } x^{2}+y^{2}+4 x+2 y=1
$$

at right angles (cf. Art. 100).
23. Given the two circles

$$
x^{2}+y^{3}-4 x-2 y+4=0 \text { and } x^{3}+y^{2}+4 x+2 y-4=0
$$

find the equations of their common tangents.
24. Find the radical axis of the circles in example 23; show that it is perpendicular to the lime joining the centers of the giren cirsles, and find the ratio of the leugths of the segments into which the radical axis diviles the line joining the cemters. How is this ratio related to the sadn of the circles? Is this relation true for any pair of circles whatever?
25. Given the three circles:

$$
x^{3}+y^{3}-16 x+60=0, \quad 3 x^{8}+3 y^{2}-80 x+81=0,
$$

and

$$
x^{3}+y^{4}-16 x-12 y+84=0
$$

find the point from which tangents draws to these three circles are of equal length, also find that length. How is this point related in position to the radical center of the given circles? Prove that this relation is the name for any three circles.
26. Find the locus of a point which moves so that the length of the tangent, drawn from it to a fixed circle, is in a constant ratio to the distance of the moving proint from a given fixed point.
27. Let $P$ be a fixed point on a given circle, $T$ a point moving along the circle, and $Q$ the point of intersection of the tangent at $T$ with the jurpendicular upon it from $P$; find the locus of $Q$.

Sicianstios. Ese polar coobrdinates, $P$ being the prole, and the dianeter through $P$ the initial line.
28. Find the length of the common chord of the two circles

$$
(x-a)^{2}+(y-b)^{2}=r^{3} \text { and }(x-b)^{2}+(y-a)^{2}=r^{2} .
$$

From this find the condition that these cireles shall towech each other.
29. If the axes are inclined at $60^{\circ}$, prove that the equation

$$
x^{2}+x y+y^{2}-4 x-5 y-2=0
$$

ropresents a circle; find its rallius and center.
30. What is the obliquity of the axes if the equation

$$
x^{2}+\sqrt{8} x y+y^{2}-4 z-6 y+5=0
$$

represents a circle? What is its radius?
31. For what point on the circle $x^{2}+y^{3}=9$ are the subtangent and the subtiormal of equal length? the tangent and wormal? the tangent and subtangent?
32. An equilateral triangle is inscribed in the circle $x^{2}+y^{2}=4$ with its base parallel to the $x$-axis; through its vertices tangents to the circle are drawn, thus forming a circumscribed triangle; find the equations, and the lengths, of the sides of each triangle.
33. The poles of the sides of each triangle in example 32 are the vertices of a triangle; find the equations of its sides, and draw the figure.
34. A chord of the circle $x^{2}+y^{2}-22 x-4 y+25=0$ is of length $4 \sqrt{ } 5$, and is parallel to the line $2 x+y+7=0$; find the equation of the chord, and of the normals at its extremities.
35. Find the equation of a circle through the intersection of the circles $x^{2}+y^{2}-4=0, x^{2}+y^{2}-2 x-4 y+5=0$, and tangent to the line $x+y-3=0$.
36. The length of a tangent, from a moving point, to the circle $x^{2}+y^{2}=6$ is always twice the length of the tangent from the same point to the circle $x^{2}+y^{2}+3(x+y)=0$. Find the equation of the locus of the moving point.
37. Find the locus of the vertex of a triangle having given the base $=2 a$, and the sum of the squares of its sides $=2 b^{2}$.
38. Find the locus of the middle points of chords drawn through a fixed point on the circle $x^{2}+y^{2}=a^{2}$.
39. Through the external point $P_{1} \equiv\left(x_{1}, y_{1}\right)$, a line is drawn meeting the circle $x^{2}+y^{2}=a^{2}$ in $Q$ and $R$; find the locus of middle point of $P_{1} Q$ as this line revolves about $P_{1}$.
40. A point moves so that its distance from the point $(1,3)$ is to its distance from the point $(-4,1)$ in the ratio $2: 3$. Find the equation of its locus.
41. Do the circles

$$
4 x^{2}+4 y^{2}+4 x-12 y+1=0 \text { and } 2 x^{2}+2 y^{2}+y=0
$$

intersect? Show in two ways.
42. Find the equation of a circle of radius $\sqrt{85}$ which passes through the points $(2,1)$ and $(-8,4)$.
43. What are the equations of the tangent and the normal to the circle $x^{2}+y^{2}=13$, - these lines passing through the point $(2,-3)$ ? through the point $(0,6)$ ?
44. Find the equations of the tangents through $(2,3)$ to the circle

$$
9\left(x^{2}+y^{2}\right)+6 x-12 y+4=0
$$

45. At what angle do the circles $x^{4}+y^{3}+6 z-29+5 \cdot 5=0$ and $x^{2}+y^{3}+1 x+2 y-6=0$ intornert each other ?
46. A diameter of the circle $4 x^{2}+4 y^{3}+8 x-12 y+1=0$ panans throngh the print $(1,-1)$. Find its equation, and thee equation of the chonds which if bisects.
47. Find the locus of a point such that tangonta from it to two conscontric circles are insersely pruprortional to the radii of the cireles.
48. Frind the locus of a point which moven mo that its distances from iwa fised proints are in constant ratio \&: Discuss the locus and draw the figure.
49. A point moves so that the syuane of itn distance from the have of ans isosceles triangle is equal to the product of its dintanees from the wher two sides. Show that the locus in a circle.
50. Prove that the two circless

$$
x^{2}+y^{2}+2 G_{1} x+2 F_{1} y+C_{1}=0 \text { and } x^{2}+y^{2}+2 G_{g^{2}} z+2 F_{y} y+C_{2}=0
$$

are concentric if $\sigma_{1}=\sigma_{3}$ and $F_{1}=F_{3}$; that they are tangent to each other if

$$
\sqrt{\left(G_{1}-G_{2}\right)^{2}+\left(F_{1}-F_{2}\right)^{2}}=\sqrt{G_{1}^{3}+F_{1}^{2}-C_{1}} \pm \sqrt{1_{2}^{3}+F_{2}^{2}-C_{2}} ;
$$

and find the condition among the constants that these circles intersect orthogonally, i.e., at right angles to each other.

## CHAPTER VIII

## THE CONIC SECTIONS

101. In Art. 48, which should now be carefully re-read, a conic section was defined; its general equation was derived; its three species, viz., the parabola, ellipse, and hyperbola, were mentioned; and a brief discussion of the nature and forms of the curve was given. In the present chapter, each of these three species will be examined somewhat more closely than was done in Chapter IV, and some general theorems concerning its tangents, normals, diameters, chords of contact, and polars will be proved.

The general equation (Art. 48) of the conic section might here be assumed, and the special forms for the parabola, the ellipse, and the hyperbola be derived from it; but, partly as an exercise, and partly for the sake of freedom to choose the axes in the most advantageous ways, the equations will here be re-derived, as they are needed, from the definitions of the curves.

## L. THE PARABOLA

## Special Equation of Second Degree

$$
A x^{2}+2 G x+2 F y+C=0, \text { or } B y^{2}+2 G x+2 F y+C=0
$$

102. The parabola defined. A parabola is the locus of a point which moves so that its distance from a fixed point, called the focus, is equal to its distance from a fixed line,
called the directrix. It is the conic section with eccentricity $e=1$ (ef. Art. 48).

The equation of a parabola, with any given focus and directrix, can be obtained directly from this definition.

Example. To find the equation of the parahola whose directris is the line $x-2 y-1=0$, and whase focus is the point $(2,-3)$.
tat $P$ im $(z, y)$ le any point on the parabolu(ses Fig. TD);
then $\frac{x-2 y-1}{+\sqrt{5}}$ is the dintance of $P^{\prime}$ from the directrix (Art. 01),
anal $\sqrt{(x-2)^{2}+(y+3)^{2}}$ is the distance of $P$ from the focus (Art. 26);
herice $\frac{x-2 y-1}{+\sqrt{5}}=\sqrt{(x-2)^{2}+(y+3)^{2}}$, by definition;
that is,

$$
4 x^{3}+4 x y+y^{2}-18 x+26 y+64=0 ;
$$

which is the required equation.
The equation obtained in this way is not, however, in the most suitable form from which to study the properties of the curve, but can be simplified by a proper choice of axes. In Art. 48 it was shown that the parabola is symmetrical with respect to the straight line through the focus and perpendicular to the directrix, and that it cuts this line in only one point. If this line of symmetry is taken as the $x$-axis, the equation will have no $y$-term of first degree $[\mathrm{cf} . \mathrm{Art} .48$, eq. (3)]; while if the point of intersection of the curve with this axis be taken as origin, the equation will have no constant term, since the point $(0,0)$ must satisfy the equation. With this choice of axes, the equation of the parabola will realuce to a simple form, which is usually called the forst standard equation of the parabola.
103. First standard form of the equation of the parabola. Let $D^{\prime} D$ be the directrix of the parabola, and $F$ its focus ;

also let the line $Z F X$, perpendicular to the directrix, be the $x$-axis; denote the fixed distance $Z F$ by $2 p$, and let $O$, its middle point, be the origin of coördinates; then the line $O Y$, perpendicular to $O X$, is the $y$-axis. Let $P \equiv(x, y)$ be any point on the curve, and draw $L Q P$ perpendicular to $O Y$, also draw the ordinate $M P$, and the line $F P$. The line $F P$ is called the focal radius of $P$.

Then

$$
\begin{equation*}
Z O=O F=p \tag{1}
\end{equation*}
$$

and the equation of the directrix is $x+p=0$,
while the focus is the point $(p, 0)$.
Again, from the definition of the parabola,

$$
F P=L P ; \text { [geometric equation }]
$$

but $F P=\sqrt{(x-p)^{2}+y^{2}}$, and $L P=Z O+O M=p+x$;
hence

$$
\sqrt{(x-p)^{2}+y^{2}}=(x+p)
$$

whence

$$
\begin{equation*}
y^{2}=4 p x \tag{41}
\end{equation*}
$$

which is the desired equation.
This first standard form [41] is the simplest equation of the parabola, and the one which will be most used in the subsequent study of the curve. It will be seen later (Chapter XII) that any equation which represents a parabola can be reduced to this form.
104. To trace the parabola $y^{2}=4 p x$. From equation [41] it follows :
(1) That the parabola passes through the point $O$, half way from the directrix to the focus. This point is called the vertex of the curve.
(2) That the parabola is symmetrical with regard to the
$x$-axis ; i.e., with regard to the line through the focus perpendicular to the directrix; this line is called the axis ${ }^{*}$ of the curve.
(3) That $x$ has always the same sign as the constant $p_{1}$ i.e., that the entire curve and its focus lie on the same side of a line parallel to the directrix, and midway between the directrix and the focus.
(t) That $x$ may vary in magnitude from 0 to $\infty$, and when $x$ increases, so also does $y$ (numerically); hence the parabola is an open curve, receding indefinitely from its directrix and its axis.

The parabola is then an open curve of one branch which lies on the same side of the directrix as does the focus ; when constructed it has the form shown in Fig. 76.
105. Latus rectum. The chord through the focus of a conic, parallel to the directrix, is called its latus rectum. In the figure this chord is $R^{\prime} R$.
Now

$$
R^{\prime} R=2 F R=2 S R=2 Z F=4 p
$$

Hence the length of the latus rectum of the parabola is $4 p$; that is, it is equal to the coefficient of $x$ in the first standard equation.
106. Geometric property of the parabola. Second standard equation. Equation [41] may be interpreted as stating an intrinsie property of the parabola, - a property which belongs to every point of the parabola, whatever cooirdinate axes be chosen. For (see Fig. 76) the equation $y^{2}=4 p x$ gives the geometric relation

$$
M P^{3}=4 O F \cdot O M=R^{\prime} R \cdot O M
$$

or, expressed in words,

[^30]If from any point on the parabola, a perpendicular is drau'n to the axis of the curve, the square on this perpendicular is equivalent to the rectangle formed by the latus rectum and the line from the vertex to the foot of the perpendicular.

This geometric property enables one to write down immediately the equation of the parabola, whenever the axis of the curve is parallel to one of the coördinate axes.
$\boldsymbol{E} . g .$, if the vertex of the parabola is the point $A \equiv(h, k)$, and its axis is parallel to the $x$-axis, as in the figure, let $F$ be the focus and $P \equiv(x, y)$

Fig. 77. be any point on the parabola; draw $M P$ perpendicular to the axis $A K$. Then

$$
\begin{gathered}
\overline{M P^{2}}=4 A F \cdot A M \\
\text { i.e., } \quad(\boldsymbol{y}-\boldsymbol{k})^{2}=4 \boldsymbol{p}(\boldsymbol{x}-\boldsymbol{h}), \cdot[42]
\end{gathered}
$$

which is the equivalent algebraic equation. This may be taken as a second standard form of the equation, representing the parabola with vertex at the point $(h, k)$, with axis parallel to the $x$-axis, and, if $p$ is positive, lying wholly on the positive side of the line $x=h$.

Equation [42] evidently may be reduced to equation [41] by a transformation of coördinates to parallel axes through the vertex $(h, k)$, as the new origin.

Again, suppose the position of the parabola to be that represented in Fig. 78. The vertex is $A \equiv(h, k)$, and the axis of the parabola is parallel to the $y$-axis. Let $P \equiv(x, y)$ he any point on the curve, and draw MP perpendicular to the axis of the curve.
Then

$$
\begin{aligned}
\overline{M P^{2}} & =4 A F \cdot A M & {[\text { geometric property }] } \\
& =4 p \cdot A M, & {[\text { here } p \text { is negative }] }
\end{aligned}
$$

Whences substituting the coriolinates of $A$ and $P$,

$$
\begin{equation*}
(x-\lambda)^{2}=4 p(y-k), \tag{48}
\end{equation*}
$$

which is another form for the second standard equation of the parabola.

## EXERCISES

Construct the following parabolas, and find their equations:

1. having the fowes at the pwint ( 1,3 ), and for disectrix the line $8 x-5 y=2$ (cf. Art. 102) ;
2. having the focus at the origin, and for directrix the line

$$
2 x-y+3=0 ;
$$

3. with the vertex at the origin, and the focus at the point (3, 0);
4. with the vertex at the origin, and the focus at the point $(0,-3)$;
5. with the vertex at the print ( 2,5 ), and the fucus at the point (-2, 1);
6. with the vertex at the point $(2,4)$, and the foens at the print ( $(1,-4)$;
7. having the foens at the point $(2 p, 0)$, and for directrix the line $s=0$ 。
8. What is the latus rectum of each of the paraholas of exercises 3 to 18.
9. Describe the effect produced on the form of a parabola by increasing or decreasing the length of its latus rectum.
10. Every equation of the form $A x^{2}+2 G x+2 F y+C=0$, or $B y^{2}+2 G x+2 F^{\prime} y+C=0$, represents a parabola whose axis is parallel to one of the coordinate axes.

Equations [41] [42], and [43] are of the form
$B y^{2}+2 G x+2 F y+C=0$, or $A x^{2}+2 G x+2 F y+C=0$;
that is, each has one and only one term containing the square of a variable, and no term containing the product of the two variables. Conversely, it may be shown that an equation of either of these forms represents a parabola whose axis is parallel to one of the coördinate axes.

A numerical example will first be discussed, by the method which has already been employed in comection with the equation of the circle (Art. 79), and which is applicable also in the case of the other conics. It is the method of reducing the given equation to a standard form, and is analogous to "completing the square" in the solution of quadratic equations.

Example. Given the equation

$$
25 y^{2}-30 y-50 x+89=0,
$$

to show that it represents a parabola; and to find its vertex, focus, and directrix.

Divide both members of the equation by 25 , and complete the square of the $y$-terms; the equation may then be written

$$
\begin{aligned}
y^{2}-\frac{5}{8} y+\frac{2}{5} & =2 x-1 \frac{1}{3}+\frac{9}{55}, \\
\left(y-\frac{3}{2}\right. & =2\left(x-\frac{f}{8}\right), \\
\left(y-\frac{8}{5}\right)^{2} & =4 \cdot \frac{1}{3} \cdot\left(x-\frac{1}{3}\right) .
\end{aligned}
$$

that is, whence

Now this equation is in the second standard form (cf. equation [42]), and therefore every point on its locus has the geometric property given in Art. 108; and the locus is a parabola. The vertex is at the point ( $, \mathrm{B}, \mathrm{B}$; its axis is parallel to the $x$-axis, extending in the positive directimn; and, since $p=\frac{1}{2}$, its focus is at the point ( $\left\{\frac{1}{2}, b\right)$, and the directrix is the line $x=H 8$.

Consider now the general equation, and apply the same method, taking for example the second form, viz. :

$$
A x^{2}+2 G x+2 F y+C=0
$$

Dividing both numbers of the equation by $A$, completing the square of the $x$-terms, and transposing, the equation becomes

$$
x^{2}+2 \frac{G}{A} x+\frac{G^{2}}{A^{2}}=-2 \frac{F}{A} y-\frac{C}{A}+\frac{C^{2}}{A^{2}}
$$

that is, $\quad\left(x+\frac{G}{A}\right)^{2}=-\frac{2 F}{A}\left(y-\frac{G^{2}-A C}{2 A F}\right)$.
whence $\quad\left(x+\frac{G}{A}\right)^{2}=4\left(-\frac{F}{2 A}\right)\left(y-\frac{G^{2}-A C}{2 A F}\right)$.
Comparing this equation with the standard equation [43]. it is seen that its locus is a parabola, whose axis is parallel to the $y$-axis, extending in the negative direction if $\boldsymbol{A}$ and $\boldsymbol{P}$ have like signs, and in the positive direction if $A$ and $F$ have unlike signs. Its vertex is at the point $\left(-\frac{G}{A} \cdot \frac{G^{2}-A C}{2 A F}\right)$; and, since $p=-\frac{F}{\underline{Q} A}$, its focus is at the point

$$
\left(-\frac{G}{A} \cdot \frac{G^{2}-F^{2}-A C}{2 A P}\right)
$$

and its directrix is the line $y=\frac{G^{2}+F^{2}-A C}{2 A F}$.
Nots. The transformation just given fails if $A=0$ or if $F=0$, for in that case some of the terms in the last equation are infinite. If, however, $A=0$, the given equation becomes $2 G x+2 F y+C=0$; and, this being of the first degree, represents a straight line. 1f, on the other Land, $F=0$, the given equation reduces to $A x^{2}+2 G i s+C=0$, and ropresents two straight lines each parallel to the $y$-axis: they are real and distinct, real and coincident, or imaginary, depending upoo the value of $G^{2}-A C$. These lines may be regarded as limiting forms of the parabola (500 Chapter XII).

## EXERCISES

Determine the vertex, focus, latus reetum, equation of the directris and of the axis for each of the following parabolas; also sketch each of the figures:

1. $y^{3}-3 x+4 y-10=0$;
2. $3 x^{2}+12 x+4 y-8=0$;
3. $3 y-1=3 y^{3}+4 x$;
4. $y^{3}+2 y-12 x-11=0$.
5. Reduction of the equation of a parabola to a standard form. In Art. 10r2 it was shown that the equation of a paralnola having any SAR. АХ. बहом. - 12
given directrix and focus is in general not as simple as the standard equation. It will now be shown that if the coordinate axes be transformed so as to be parallel to the axis and
 directrix of the curve, the equation will be reduced to a standard form. For example, the equation of the parabola with focus at $(2,-3)$, and having for directrix the line $x-2 y-1=0$, was found to be

$$
4 x^{2}+4 x y+y^{2}-18 x+26 y+64=0
$$

The axis of the curve is a line through $(2,-3)$ and perpendicular to

$$
x-2 y-1=0 ;
$$

its equation is $2 x+y=1$, and it cuts the $x$-axis at the angle $\theta=\tan ^{-1}(-2)$.
The point $Z$ is the intersection of the directrix and axis, and may be found from the two linear equations representing these lines; the vertex $A$ is the point bisecting $Z F$. If, then, the axes are rotated through the angle $\theta=\tan ^{-1}(-2)$, the equation will be reduced to the second standard form, [42]; and if the origin be also removed to the vertex $A$, the equation will be further reduced to the first standard form, [41]. The point $Z$ is $\left(\frac{b}{5},-\frac{1}{8}\right), A$ is $\left(\frac{18}{8},-\frac{1}{8}\right)$; hence, $p=A F=\frac{7}{2 \sqrt{5}}$, and transforming the axes through the angle $\theta=\tan ^{-1}(-2)$, to the new origin $\left(\frac{18}{8},-\frac{1}{8}\right)$, the equation of the parabola reduces to $y^{2}=\frac{14}{\sqrt{5}} x$.

The problem of reducing any equation representing a parabola to its standard form is taken up more fully in Chap. XII.

## EXERCISES

Find, and reduce to the first standard form, the equation of each of the following parabolas ; also make a sketch of each figure:

1. with focus at the point $(-1,3)$, and having for directrix the line

$$
3 x-5 y=2 ;
$$

2. with focus at the point $\left(-8,-\frac{1}{2}\right)$, and having for directrix the line

$$
2 x+7 y-8=0 ;
$$

3. with focus at the point $(a, b)$, and having for directrix the line

$$
\frac{x}{a}+\frac{y}{b}=1
$$

## 11. TIIF EIJ.IIS:

## Spectial Equation of the Second Degree

$$
A x^{2}+13 y^{2}+26 x+2 F y+C=0
$$

109. The ellipse defined. An ellipse is the locus of a point which moves so that the ratio of its distance from a fixed point, called the focus, to its distance from a fixed line, called the directrix, is constant and less than unity. The constant ratio is called the eccentricity of the ellipse. This curve is the conie section with eccentricity $e<1$. (ef. Art. 48.)

The equation of an ellipse with any given focus, directrix, and eocentricity may be readily obtained from this definition.

Examples. An ellipee of eceentricity ; has its focus at (2, -1) and has the line $x+2 y=5$ for directrix. Let $P \equiv(5, y)($ Fig. 85i) he any point on the curve, $F$ the focus, and $P Q$ the perpendicular from $P$ to the direotris.

Then

$$
F P=1 Q P ;
$$

Lat $F P=\sqrt{(x-2)^{3}+(y+1)^{2}}, Q P=\frac{x+2 y-5}{+\sqrt{5}} \quad$ (Arta 20,64),
hence

$$
(x-2)^{2}+(y+1)^{2}=\frac{1}{n}(x+2 y-5)^{2} ;
$$

that is, $\quad 41 x^{2}-16 x y+29 y^{3}-140 x+170 y+125=0$;
wheh is the equation of the given ellipse.
As in the case of the parabola, so also here, a particular choice of the courdinate axes gives a simpler form for the equation of the ellipse; an equation which is more suitable for the study of the curve, and to which every equation representing an ellipse can be reduced. As has been seen in Art. 48, the curve is symmetrical with respeet to the line throngh the focus and perpendicular to the directrix: and cuts that line in two points, one on cither side of the fincus. The equation of the ellipse will be in a simpler form if this
line of symmetry is chosen as the $x$-axis, with the origin half way between its two points of intersection with the curve. The resulting equation is the first standard form of the equation of the ellipse.
110. The first standard equation of the ellipse. Let $F$ be the focus, $D^{\prime} D$ the directrix, and $Z F^{\prime} X$ the perpendicular to $D^{\prime} D$
 through $F$, cutting the curve in the two points $A^{\prime}$ and $A$ (Art. 48)*. Denote by $2 a$ the length of $A A^{\prime}$, and let $O$ be its middle point, so that

$$
A O=O A^{\prime}=a
$$

Let $Z X$ be the $x$-axis, $O$ the origin, and $O Y$, perpendicular to $O X$, the $y$-axis. Then, by the definition of the ellipse,

$$
A F=e Z A, \quad \text { and } \quad F A^{\prime}=e Z A^{\prime}
$$

$\therefore \quad A F+F A^{\prime}=e\left(\boldsymbol{Z} A+\boldsymbol{Z} A^{\prime}\right)=e\left(\boldsymbol{Z} A+\boldsymbol{Z} A+\boldsymbol{A} \boldsymbol{A}^{\prime}\right)$,
i.e., $\quad A A^{\prime}=e\left(2 Z A+A A^{\prime}\right)$,
whence $\quad 2 a=2 e(Z A+A O)=2 e Z O$;
therefore $\quad Z O=\frac{a}{e}$,
and the equation of the directrix is $x+\frac{a}{e}=0$.
Again,

$$
\begin{equation*}
F A^{\prime}-A F=e\left(Z A^{\prime}-Z A\right) \tag{1}
\end{equation*}
$$

i.e.,
whence

$$
F O+O A^{\prime}-(A O-F O)=e A A^{\prime}
$$

$$
2 F O=2 a e
$$

- This equation may also be easily derived independently of Art. 48, cf. Arts. 108, 116.
therefore

$$
\begin{equation*}
F O=a e, \tag{2}
\end{equation*}
$$

and the focus $F^{7}$ is the point $(-a e, 0)$.
Now, for any point $P$ ' on the curve, draw the ordinate $M P$ and the perpendicular $L . P$ to the directrix ; then

$$
\begin{equation*}
F P=-I . P, \quad[\text { geometric equation }] . \tag{3}
\end{equation*}
$$

but $F P=\sqrt{(x+a e)^{2}+y^{3}}, L P=\frac{a}{e}+x$;
hence

$$
\begin{equation*}
(a e+x)^{2}+y^{2}=e^{2}\left(x+\frac{a}{e}\right)^{2} \tag{4}
\end{equation*}
$$

that is,

$$
\begin{equation*}
\left(1-e^{2}\right) x^{2}+y^{2}=a^{2}\left(1-e^{b}\right) \tag{5}
\end{equation*}
$$

that is,

$$
\begin{equation*}
\frac{x^{3}}{a^{2}}+\frac{y^{2}}{a^{2}\left(1-e^{3}\right)}=1 \tag{6}
\end{equation*}
$$

From equation (6), the intercepts of the curve on the $y$-axis are $\pm a \sqrt{1-e^{2}}$. Both intercepts are real, since $e<1$; hence the ellipse cuts the $y$-axis in two real points, $B$ and $B^{\prime}$, on upposite sides of the origin $O$ and equidistant from it. If $O B$ is denoted by $+b$, so that

$$
\begin{equation*}
b^{2}=a^{2}\left(1-c^{2}\right), \quad . \quad . \tag{7}
\end{equation*}
$$

equation (6) takes the form

$$
\begin{equation*}
\frac{x^{2}}{a^{2}}+\frac{y^{2}}{b^{2}}=1 \tag{44}
\end{equation*}
$$

This is the simplest equation of the ellipse, and will be most used in the subsequent study of the properties of that curve. As will be seen in Chapter XII, every equation representing an ellipse can be reduced to this form.

[^31]111. To trace the ellipse $\frac{x^{2}}{a^{2}}+\frac{y^{2}}{b^{2}}=1$. From equation [44] it follows that :
(1) The ellipse is symmetrical with regard to the $x$-axis ; i.e., with regard to the line through the focus and perpendicular to the directrix; this line is therefore called the principal axis of the curve;
(2) The ellipse is symmetrical with regard to the $y$-axis also ; i.e., with regard to a line parallel to the directrix and passing through the mid-point of the segment $A A^{\prime}$ (Fig. 81) which the curve cuts from its principal axis;
(3) For every value of $x$ from $-a$ to $+a$, the two corresponding values of $y$ are real, equal numerically, but opposite in sign ; and for every value of $y$ from $-b$ to $b$, the two values of $x$ are real and equal numerically, but opposite in sign ; and that neither $x$ nor $y$ can have real values beyond these limits.

The ellipse is, therefore, a closed curve, of one branch, which lies wholly on the same side of the directrix as the focus ; and the curve has the form represented in Fig. 80, - which agrees with the foot-note on p. 71.

The segment $\boldsymbol{A} \boldsymbol{A}^{\prime}$ (Fig. 81) of the principal axis intercepted by the curve is called its major or transverse axis;
the corresponding segment $B^{\prime} B$ is its minor or conjugate axis. From the symmetry of the curve with respect to these ases it follows that it is also symmetrical with respect to their intersection $O$, the center of the ellipse. It follows also that the ellipse has a second focus at $F^{\prime}=(a, 0)$ ( Fig. 81) and a second directrix $D_{1} D_{1}$ - the line $x-\frac{a}{e}=0$ - on the posilive side of the minor axis, and symmetrical to the origimal focus and directrix, respectively. ${ }^{*}$

The latus rectum of the ellipse, i.e., the focal chord parallel to the directrix (Art. 105), is evidently twice the ordinate of the point whose abscissa is ae.

But if $x_{1}=a e, y_{1}=b \sqrt{1-e^{2}}$; or, since $b=a \sqrt{1-e^{2}}$, $y_{1}=\frac{b^{2}}{a}$. Hence the latus rectum is $\frac{2 b^{2}}{a}$.
112. Intrinsic property of the ellipse. Second standard equation. Equation [44] states a geometric property which belongs to every point of the ellipse, whatever the coordinate axes chosen, and to no other point : viz., if $\boldsymbol{P}$ be any point of the ellipse (Fig. 80), then
that is, in words :

$$
\frac{\overline{O M^{2}}}{\overline{O A^{2}}}+\frac{\overline{M P^{2}}}{\overline{O S^{2}}}=1
$$

- To show this analytically, let $O P^{\prime}=a e$, and $O Z^{\prime}=\frac{a}{8}$, and let $P \equiv(x, y)$ be any point on the ellipee, as before. Equation (4) of Art. 110 , gives the relation between $x$ and $y$; expanding equation ( $f$ ), and subtracting 4 arz Irom each member, it becomes

$$
a^{2} e^{2}-2 a e x+x^{2}+y^{3}=a^{3}-2 a e x+e^{2} x^{2}
$$

which may be written
6.

$$
\begin{gathered}
(a e-x)^{2}+y^{2}=e^{3}\left(\frac{a}{e}-x\right)^{2}, \\
\overline{F P^{2}}=e^{e} \overline{P b^{2}} ;
\end{gathered}
$$

Whirh shows that $P$ is on an ellipee whose foeus is $F^{V}$ and whose directrix is $D_{1}^{\prime} D_{1}$.

If from any point on the ellipse a perpendicular be drawn to the transverse axis; then the square of the distance from the center of the ellipse to the foot of this perpendicular, divided by the square of the semi-transverse axis, plus the square of the perpendicular divided by the square of the semi-conjugate axis, equals unity.

This geometric or physical property belongs to no point not on the curve, and therefore completely determines the ellipse. It enables one to write immediately the equation of any ellipse whose axes are parallel to the coördinate axes.

For example: if, as in Fig. 82, the major axis of an ellipse is parallel to the $x$-axis, and the center is at the point

$C \equiv(h, k)$, let $P \equiv(x, y)$ be any point on the curve, and $a, b$ be the semi-axes, then
that is

$$
\begin{gather*}
\frac{\overline{C M}^{2}}{\overline{C A}^{2}}+\frac{\overline{M P}^{2}}{\overline{C B}^{2}}=1, \\
\frac{(\boldsymbol{x}-\boldsymbol{h})^{2}}{a^{2}}+\frac{(y-\boldsymbol{k})^{2}}{b^{2}}=\mathbf{1}, \tag{45}
\end{gather*}
$$

which is the equation of the given ellipse.
Or again, if, as in Fig. 83, the major axis is parallel t1 the $y$-axis ; then, as before

$$
\frac{\overline{C M}^{2}}{\overline{C A}^{2}}+\frac{\overline{M P}^{2}}{\overline{C B}^{2}}=1,
$$

i.8., $\frac{(y-k)^{2}}{a^{2}}+\frac{(x-h)^{8}}{b^{2}}=1,[46]$ which is the equation of the given ellipse.

Equation [45] may be considered a second standard form of the equaLion of the ellipse ; by a change of courdinates to a set of parallel axes through the center $C \equiv(h, k)$, as the new origin, it can be reduced to the first standard form.

By Art. 110 the distance from the center of an ellijse to its focus is ae ; but since $b^{2}=a^{2}\left(1-e^{2}\right)^{\text {e }}$
 [Art. 110, eq. (i)], therefore $a e=\sqrt{a^{2}-b^{2}}$; hence, in Figs 82 and 83 ,

$$
F^{\prime} C=C F=a e=\sqrt{a^{3}-b^{2}} .
$$

Again, the equation of an ellipse, in either standard form, gives the semi-axes as well as the center of the curve, therefore the positions of the foci are readily determined from either standard form of the equation.

## EXERCISES

Construet the following ellipees, and find their equations:

1. given the focus at the point $(-1,1)$. the equation of the directrix $z-y+3=0$, and the eccentricity ( cf . Art. 1099) :
2. given the focus at the origin, the equation of the directrix $x=-2$. and the eccentricity f:

[^32]3. given the focus at the point $(0,1)$, the equation of the directrix $y-25=0$, and the eccentricity f;
4. given the center at the origin, and the semi-axes $\sqrt{2}, \sqrt{5}$. Find also the latus rectum.

Find the equation of an ellipse referred to its center, whose axes are the coördinate axes, and
5. which passes through the two points $(2,2)$ and $(3,1)$.
6. whose foci are the points $(3,0),(-3,0)$, and eccentricity t.
7. whose foci are the points $(0,6),(0,-6)$, and eccentricity ?.
8. whose latus rectum is 5 , and eccentricity 3 .
9. whose latus rectum is 8 , and the major axis 10 .
10. whose major axis is 18 , and which passes through the point 6,4 .

Draw the following ellipses, locate their foci, and find their equations:
11. given the center at the point $(3,-2)$, the semi-axes 4 and 3 , and the major axis parallel to the $x$-axis (cf. Art. 112);
12. given the center at the point $(-8,1)$, the semi-axes 2 and 5 , and the major axis parallel to the $y$-axis ;
13. given the center at the point $(0,7)$, the origin at a vertex, and $(2,3)$ a point on the curve;
14. given the circumscribing rectangle, whose sides are the lines $x+1=0,2 x-3=0, y+6=0,3 y+4=0$; the axes of the curve being parallel to the coördinate axes.
15. If $b$ becomes more and more nearly equal to $a$, what curve does the ellipse approach as a limit?
113. Every equation of the form $A x^{2}+B y^{2}+2 G x+2 F y$ $+\boldsymbol{C}=\boldsymbol{O}$, in which $\boldsymbol{A}$ and $\boldsymbol{B}$ have the same sign, represents an ellipse whose axes are parallel to the coördinate axes. Equations [44], [45], and [46], obtained for the ellipse, are all, when expanded, of the form

$$
\begin{equation*}
A x^{2}+B y^{2}+2 G x+2 F y+C=0 \tag{1}
\end{equation*}
$$

where $A$ and $B$ have the same sign, and neither of them is zero. Conversely, an equation of this form represents an ellipse
whos axes are parallel to the complinate axes. As in Art. 107, a numerical case will first be examined, and then the general equation taken up in a similar manner.

Example, Given the equation $4 x^{3}+9 y^{3}-18 x+18 y-11=0$, to show that it represonts an ellipse, and to find its elements. Completing

the square for the terms in $x$, and also for those in $y$, and transposing, this equation becomes

$$
4 x^{2}-16 x+16+9 y^{2}+18 y+9=11+16+9
$$

that is,

$$
\begin{gathered}
4(x-2)^{2}+9(y+1)^{2}=36 ; \\
\frac{(x-2)^{2}}{3^{2}}+\frac{(y+1)^{2}}{2^{3}}=1 .
\end{gathered}
$$

This equation is of the form [45], and, therefore, its locus has the gesmetric property given in Art. 112, and is an ellipse. Its eenter is the point $(2,-1)$ : its major axis is parallel to the $x$-axis, of length 6 : its minor axis is of length 4; the foci are the points

$$
F=(2-\sqrt{5},-1), F=(2+\sqrt{8},-1) ;
$$

and the equations of the directrices are, respectively,

$$
x=2+\frac{9}{\sqrt{5}}, \quad x=2-\frac{9}{\sqrt{5}} .
$$

Following the methol illustrated above, of completing the squares, the general equation (1) may be written
$A\left(x^{2}+2 \frac{G}{A} x+\frac{G^{2}}{A^{2}}\right)+B\left(y^{2}+2 \frac{F}{B} y+\frac{F^{2}}{B^{2}}\right)=-C+\frac{G^{2}}{A}+\frac{F^{2}}{B}$.
that is,

$$
A\left(x+\frac{G}{A}\right)^{2}+B\left(y+\frac{F}{B}\right)^{2}=\frac{B G^{2}+A F^{2}-A B C}{A B}
$$

which becomes, if the second member be represented by $K_{\text {. }}$.

$$
\begin{equation*}
\frac{\left(x+\frac{G}{A}\right)^{2}}{\frac{K}{A}}+\frac{\left(y+\frac{F}{B}\right)^{2}}{\frac{K}{B}}=1 \tag{2}
\end{equation*}
$$

Comparing this equation with [45] or [46], it is seen to express the geometric relation of Art. 112 , and therefore represents an ellipse. Its axes are parallel to the coördinate axes, its center is at the point $\left(-\frac{G}{A},-\frac{F}{B}\right)$, and the lengths of the semi-axes are

$$
\sqrt{\frac{K}{A}}, \quad \sqrt{\frac{K}{B}}
$$

The foci and directrices may be found as above.
Nots. If $A=B$, then equation (1) represents a circle (Art. 79). If $A B C>B G^{2}+A F^{2}$, equation (1) having been written with $A$ and $B$ positive, then no real values of $x$ and $y$ can satisfy equation (2), which is only another form of equation (1), and it is said to represent an imaginary ellipse. If $A B C=B G^{2}+A F^{2}$, then $x=-\frac{G}{A}$, and $y=-\frac{F}{B}$ are the only real values that satisfy equation (2); in that case, this equation is said to represent a point ellipse; or, from another point of view. two imaginary lines which intersect in the real point $\left(-\frac{G^{2}}{A},-\frac{F}{B}\right)$. Each of the above may be regarded as a limiting form of the ellipse.

## EXERCISES

Determine, for each of the following ellipses, the center, semi-axes, foen, vertices, and latus rectum; then sketch each curve.

1. $3 x^{3}+9 y^{2}-6 x-97 y+2=0$
2. $4 x^{2}+y^{2}-8 x+2 y+1=0$.
3. $x^{3}+12 y^{2}+4 x+60 y+15=0$
4. By completing the squares of the s-terms and of the yterms, and a mastabile trabsformation of coordinatens, roduce the equations of exercisens 1 , 2 , and 3 to the standard form [41].

## 114. Reduction of the equation of an ellipse to a standard form.

It is now evident that, if the directrix and focus of an elliper are known, as in the example of Art. 109, the transformation of coordinates

which is necessary to reduce the equation to a standard form can easily iev intermined. To illustrate: the ellipse of eceentricity 3. with focus at Fia $(2,-1)$, and having for directrix the lise $I / 1)$, whose equation is $x \cdot 2 y=5$, has for its equation (Art. 100)

$$
41 x^{2}-16 x y+29 y^{2}-140 x+170 y+125=0
$$

Its axin $F Z$. perpendicular to $D^{\prime} D$, has the equation $2 x-y=5$, and cuts the $x$-axis at the angle $\tan ^{-1} 2$. If then the coordinate axes are rotated through the angle tan ${ }^{-1} 2$, the equation will be reduced to the secont standard form. Again, $Z$ may be found as the intersection of the directrix and axis; it is the point $(3,1)$. Then $A$ and $A$, the vertives
of the ellipso, divide $F \boldsymbol{F}$ internally and externally in the ratio $\boldsymbol{f}$; hence (Art. 30) these coordinates are $\left(\gamma^{2},-\frac{1}{8}\right),(0,-5)$. Also $C$, the center of the ellipse, is the point $(3,-\xi)$. If the origin he next transformed to the point $C$, the equation will be reduced to the first standard form. since the axis $A A$ is of length $\frac{12}{\sqrt{5}}$, and the eccentricity is 3 , the semiaxes are $\frac{6}{\sqrt{ } 5}$ and 2 ; hence the reduced equation, with $C$ as origin and CA as $x$-axis, will be

$$
\frac{x^{2}}{\frac{x^{6}}{6}}+\frac{y^{2}}{4}=1
$$

. The problem of reducing to standard form the equation of an ellipse, when the directrix is not known, will be postponed to Chapter XII.

## EXERCISES

Find, and reduce to the first standard form, the equation of the ellipse :

1. with focus at the point $(1,-3)$, with the line $x+y=7$ for directrix, and eccentricity $\frac{1}{3}$;
2. with focus at the point $(a, b)$, the line $\frac{x}{a}+\frac{y}{b}=1$ for directrix, and eccentricity $\frac{l}{n}$ (where $l<n$ ).

## III. THE HYPERBOLA

## Special Equation of the Second Degree

$$
A x^{2}-B y^{2}+2 G x+2 F y+C=0
$$

115. The hyperbola defined. An hyperbola is the locus of a point which moves so that the ratio of its distance from a fixed point, called the focus, to its distance from a fixed line, called the directrix, is constant and greater than unity. The constant ratio is the eccentricity of the hyperbola. This curve is the conic section with eccentricity $e>1$ (cf. Art. 48).

Since the hyperbola differs from the ellipse only in the sign of $1-c^{2}$, which is + in the ellipse and - in the hypers: bola, the standard equation of the hyperbola can be derived by the method of Art. 110 ; and it will be found that with choice of axes and notation as there given, the ressulis gives in eqs. (1), (2), and (3) of that article apply equally to the hyperbola. If now, since $1-e^{2}$ is negrative, the substitution $b^{2}=u^{2}\left(e^{2}-1\right)$ is made, equation (6) (p.181) will become

$$
\begin{equation*}
\frac{x^{2}}{a^{2}}-\frac{y^{2}}{b^{2}}=1 \tag{47}
\end{equation*}
$$

which is the simplest equation of the hyperbola. For variety, this equation will be obtained by a different method.
116. The first standard form of the equation of the hyperbola. Let $\boldsymbol{F}$ be the focus, IF I the directrix, and $e$ the eccentricity of the curve. Take $I^{\prime} D$ as the $y$-axis, with the perpendicular OF'X upon it, through the focus, as the $x$-axis. Let $2 p$ denote the given distance $O F$, and let

$$
P \equiv(x, y)
$$

Fro.so
be any point of the locus, with coördinates $L P$ and $M P$.

$$
\text { Then } \quad F P=e L P
$$

[geometric equation]
but

$$
\begin{aligned}
& F P=\sqrt{(x-2 p)^{2}+y^{2}}, \text { and } L P=x ; \\
& \quad(x-2 p)^{2}+y^{2}=\varepsilon^{2} x^{2} ;
\end{aligned}
$$

that is,

$$
\begin{equation*}
\left(e^{2}-1\right) x^{2}-y^{2}+4 p x-4 p^{2}=0, \tag{1}
\end{equation*}
$$

which is the equation of the hyperbola referred to its directrix and principal axis as coordinate axes (ef. Art. 48).

The curve cuts the $x$-axis in two points, $A \equiv\left(x_{1}, 0\right)$, and $A^{\prime} \equiv\left(x_{2}, 0\right)$, - the vertices of the hyperbola, - whose abscissas are determined by the equation

$$
\left(e^{2}-1\right) x^{2}+4 p x-4 p^{2}=0
$$

The abscissa of $C$, the middle point of the segment $A A^{\prime}$, is, therefore,

$$
O C=\frac{x_{1}+x_{2}}{2}=\frac{-2 p}{e^{2}-1} \quad(\text { Art. 11 })
$$

hence the center is on the opposite side of the directrix from the focus.

Now transform equation (1) to a parallel set of axes through $C$; the equations for transformation are (Art. 71)

$$
x=x^{\prime}-\frac{2 p}{e^{2}-1}, \text { and } y=y^{\prime}
$$

substituting these values, and removing accents, eq. (1) becomes

$$
\left(e^{2}-1\right)\left(x-\frac{2 p}{e^{2}-1}\right)^{2}-y^{2}+4 p\left(x-\frac{2 p}{e^{2}-1}\right)-4 p^{2}=0
$$

which reduces to $\left(e^{2}-1\right) x^{2}-y^{2}=\frac{4 y^{2} e^{2}}{e^{2}-1}$,
that is,

$$
\begin{equation*}
\frac{\frac{x^{2}}{\frac{4 p^{2} e^{2}}{\left(e^{2}-1\right)^{2}}}-\frac{y^{2}}{4 p^{2} e^{2}}}{\frac{e^{2}-1}{}}=1 \tag{2}
\end{equation*}
$$

If these denominators are represented by $a^{2}$ and $b^{2}$ respectively, i.e., if

$$
\begin{equation*}
a^{2}=\frac{4 p^{2} e^{3}}{\left(e^{2}-1\right)^{2}}, \text { and } b^{2}=\frac{4 p^{2} e^{2}}{e^{2}-1} \tag{8}
\end{equation*}
$$

then

$$
\begin{equation*}
b^{2}=a^{2}\left(e^{2}-1\right) \tag{4}
\end{equation*}
$$

and equation (2) may be written in the simple form

$$
\begin{equation*}
\frac{x^{2}}{a^{2}}-\frac{y^{2}}{b^{2}}=1 \tag{47}
\end{equation*}
$$

the standard equation of the hyperbola Every equation representing an hyperbola can be reduced to this form, as is shown in Chapter XII.
The distance from the center to the focus of the hyperhola $x^{a^{2}}-\frac{y^{2}}{l^{2}}=1$ is casily fomm thus:

$$
\begin{aligned}
C F & =C O+O F \\
& =\frac{2 p}{e^{3}-1}+2 p=\frac{2 p e^{2}}{c^{2}-1} ;
\end{aligned}
$$

but, from equation (8),

$$
a=\frac{2 p e}{e^{2}-1}
$$

hence

$$
\begin{equation*}
C F=a e, \tag{4}
\end{equation*}
$$

therefore the focus $F$ is the point (ae, 0 ).
Similarly for the directrix :

$$
C O=\frac{2 p}{e^{3}-1}=\frac{a}{e}
$$

hence

$$
\begin{equation*}
\text { the directrix is the line } x-\frac{a}{e}=0 \text {. } \tag{5}
\end{equation*}
$$

As above defined, $b$ is real, and its value is known when a and e are known. In Fig. 86,

$$
C B=b, C B^{\prime}=-b \text {, and } b=a \sqrt{c^{2}-1} .
$$

117. To trace the hyperbola $\frac{x^{2}}{a^{2}}-\frac{y^{2}}{b^{2}}=1$. Equation [4T] shows that:
(1) The hyperbola is symmetrical with regard to the $x$-axis; that is, with respect to the line through the focus and perpendicular to the directrix. This line is therefore called the principal axis of the hyperbola;
(2) The hyperbola is symmetrical with regard to the $y$-axis also; i.e., with regard to the line parallel to the directrix and passing through the mid-point of the segment cut ly the eurve from its principal axis;
(3) For every value of $x$ from $-a$ to $a, y$ is imıginary; while for every other value of $x, y$ is real and has two values, equal numerically but opposite in sign. But for every value of $y, x$ has two real values, equal numerically and opposite in sign. When $x$ increases numerically from $a$ to $\infty$, then $y$ increases also numerically from 0 to $\infty$.

These facts show that no part of the hyperbola lies between the two lines perpendicular to its principal axis and drawn through the vertices of the curve; but that it has two open infinite branches, lying outside of these two lines. The form of the hyperbola is as represented in Fig. 86.

The segment $A^{\prime} A$ of the principal axis, intercepted by the curve, is called its transverse axis. The segment $B^{\prime} B$ of the

Fig. 87 second line of symmetry (the $y$-axis), where $B^{\prime} O=O B=b$, is called the conjugate axis; and although not cut by the hyperbola, it bears important relations to the curve. From the symmetry of the hyperbola, with respect to these axes, it follows that it is also symmetrical with respect to their intersection $O$, the center of the curve. It follows also that there is a second focus at the point ( $-a e, 0$ ), and a second directrix in the line $x+\frac{a}{e}=0$ on the negative side of the conjugate axis, and symmetrical to the original focus and directrix. (See Art. 111, foot-note.)

The latus rectum of the hyperbola is readily found to be $\frac{2 b^{2}}{a}$ (cf. Arts. 105, 111).
118. Intrinsic property of the hyperbola. Second standard equation. Bquation [4i] states a geometrie jroperty which ix-longs to every point of an hyperbola, whatever the eobirdinate axes chosen, and to no other point ; and which therefore completely defines the hyperbola. With the figure and nutation of Art. 117, equation [47] states (Fig. 87)

$$
\frac{\overline{M^{2}}}{\overline{O . A^{2}}}-\frac{M D^{2}}{U J^{2}}=1
$$

a property entirely analogous to that of Art. 112 for the ellipse. It enables one to write at once the equation of an

Fia. 88

Fro.80.
hyperbola with given center and semi-axes, and axes parallel to the coordinate axes.

For example, if the transverse axis is parallel to the s-axis, as in Fig. 88, and the center at the point $\bar{C} \equiv(h, k)$. and if $P=(x, y)$ is any point on the curve, then

$$
\begin{gather*}
\frac{C M^{2}}{C A^{2}}-\frac{M P^{2}}{\overline{C b^{2}}}=1, \\
\text { i.e., } \frac{(x-h)^{2}}{a^{2}}-\frac{\left(y-k^{2}\right.}{b^{2}}=1, \quad . \tag{48}
\end{gather*}
$$

which is the equation of the hyperbola, with $a$ and $b$ as semiaxes.

Again, if the transverse axis is parallel to the $y$-axis, as in Fig. 89, with the center at the point ( $h, k$ ), the equation of the hyperbola will be found to be
i.e.,

$$
\begin{align*}
& \frac{(y-k)^{2}}{a^{2}}-\frac{(x-h)^{2}}{b^{2}}=1, \\
& \frac{(x-h)^{2}}{b^{2}}-\frac{(y-k)^{2}}{a^{2}}=-1 . \tag{49}
\end{align*}
$$

Note 1. That the expressions obtained on p. 193 for the distances from the center to the focus and the directrix, of hyperbola [47], are equally true for hyperbolas [48] and [49] follows from the fact that those expressions involve only $a, b$, and $e$; moreover, equation (4) of Art. 116 determines $e$ in terms of $a$ and $b$; hence, for all these hyperbolas, $e^{2}=\frac{a^{2}+h^{2}}{a^{2}}$ the distances from the center to the foci are given by

$$
a e= \pm \sqrt{a^{2}+b^{2}},
$$

and those to the directrices by

$$
\frac{a}{e}=\frac{a^{2}}{ \pm \sqrt{a^{2}+b^{2}}}
$$

Note 2. It should be noticed that in equations [47], [48], [49], the negative term involves that one of the coördinates which is parallel to the conjugate axis.

## EXERCISES

1. Find the equation of the hyperbola having its focus at the point $(-1,-1)$, for its directrix the line $3 x-y=7$, and eccentricity ! Plot the curve (cf. Art. 102, and Art. 109, Ex.).

Find the equation of the hyperbola whose center is at the origin and
2. whose semi-axes equal, respectively, 5 and 3 (ef. Art. 116, [47]);
3. with transverse axis 8 , -the point $(20,5)$ being on the curve;
4. the distance between the foci 5 , and eccentricity $\sqrt{2}$;
5. with the distance between the foci equal to twice the transverse axis.

Find the equation of an hyperbola
6. with center at the point $(3,-2)$, semi-axes 4 and 3 , and the transverse axis parallel to the $x$-axis. Plot the curve (cf. Art. 118);
7. with consteop at the point ( $-3,-4$ ), semi-aress 6 and 2, and them cransverne axis parallel to the $y$-axis. Plot the curves.
a. Find the foei and latun rectum for the hyperbolas of exercines 6 and 7.
9. By a muitable transformation of coordinates, reduce the equations of exercises 8 and 7 to the standard form $\frac{x^{3}}{a^{3}}-\frac{y^{3}}{b^{3}}=1$.
10. Find the foci of the hyperbolus
(a) $\frac{x^{2}}{25}-\frac{x^{2}}{9}=1$
( $\beta$ ) $\frac{x^{2}}{4}-\frac{y^{2}}{9}=1$,
(y) $\frac{y^{3}}{9}-\frac{x^{3}}{4}=1$.

I'lot the curves $(\beta)$ and $(\gamma)$.
119. Every equation of the form $A x^{2}+B y^{2}+2 C i x+2 F y$ $4 \boldsymbol{C}=0$, in which $A$ and $E$ have unlike signs, represents an hyperbola whose axes are parallel to the coordinate axes. When cleared of fractions and expanded, the three equations found for the hyperbola are of the form

$$
\begin{equation*}
A x^{2}+B y^{2}+2 G x+2 F y+C=0 \tag{1}
\end{equation*}
$$

where $A$ and $B$ have opposite signs, and neither of them is zero. Conversely, it will now be shown that every equation of this form represents an hyperbola, whose axes are parallel to the coordinate axes. A numerical case will be examined first, and then the general equation.

Examples. To show that the equation $8 x^{2}-4 y^{2}-18 x+24 y-63=0$ ropresents an hyperbola, and to find its elementa. Transposing the constant term, and completing the squares of the $x$-terms and $y$-terms, the eluation may be written

$$
\begin{gathered}
9(x-1)^{2}-4(y-3)^{2}=36 \\
\frac{(x-1)^{2}}{2^{2}}-\frac{(y-3)^{2}}{3^{2}}=1
\end{gathered}
$$

Since this equation is of the form [4s], its locus has the geometric property given in Art. 118, and therefore represents an hyperlaba. Its conter is at the point $(1,3)$, its transverse axis is parallel to the r-axis, of length 4, and its conjugate axis is of length 6. The eccentricity is $e=\$ \sqrt{ } 13$, the foci are at the points $(1-\sqrt{ } 13,3)$ and $(1+\sqrt{ } 13,3)$; and the directrices are the lines whose equations are

$$
x=1 \pm \frac{4}{\sqrt{13}}
$$

Following the method illustrated in the numerical example, the general equation (1) may be written in the form

$$
\begin{equation*}
\frac{\left(x+\frac{G}{A}\right)^{2}}{\frac{K}{A}}+\frac{\left(y+\frac{F}{B}\right)^{2}}{\frac{K}{B}}=1 \tag{2}
\end{equation*}
$$

wherein (cf. Art. 113, p. 188),

$$
K=\frac{B G^{2}+A F^{2}-A B C}{A B}
$$

Since $A$ and $B$ have opposite signs, the two terms in the first member of this equation are of opposite signs; the equation is therefore in the form of [48] or [49], and represents an hyperbola. Its axes are parallel to the coördinate axes, its center is the point $\left(-\frac{G}{A},-\frac{F}{B}\right)$, and its semi-axes are $\sqrt{ \pm \frac{K^{A}}{A}}$ and $\sqrt{ \pm \frac{K}{B}}$.

Note. Since $A$ and $B$ have opposite signs, equation (2), which is only another form of equation (1), always represents a real locus; it is an hyperbola proper except when $A B C=B G^{2}+A F^{2}$, and it then represents a pair of intersecting straight lines (cf. Art. 67).

It is clear that the method shown for the ellipse in Art. 114 can be applied equally well to the hyperbola, to reduce any equation of this curve to the standard form, when the directrix is known. The problem of reducing to the standard form the general equation of an hyperbola, when the directrix and focus are not known, is considered in full in Chapter XII.

[^33]
## EXERCISES

Determine for each of the following hyprebbolas the conter, serms-axm, fuci, vertices, and latus rectum:

1. $16 x^{3}-8 y^{3}+68 x-36 y+10=0 ;$
2. $x^{3}-5 y^{3}+15 y-10 x+1=0$;
3. $2 x+6 y+3 y^{2}=x^{3}+7$.
4. Rocluce the equations of exercises $1,2,3$, to the standard form $\frac{x^{2}}{a^{2}}-\frac{y^{2}}{b^{2}}=1$. Sketch each curve.
5. Summary. In the preceding articles it his been shown that the special equation of the second degree,

$$
A x^{2}+B y^{2}+2 G x+2 F y+C=0
$$

always represents a conic section, whose axes are parallel to the coördinate axes. There are three cases, corresponding to the three species of conie.
(1) The parabola: either $\boldsymbol{A}$ or $\boldsymbol{B}$ is zero. In exceptional cases this curve degenerates into a pair of real or imaginary parallel straight lines, and these may coincide. [Art. 107]
(2) The ellipse : neither $\boldsymbol{A}$ nor $\boldsymbol{B}$ is zero, and they have like signs. In exceptional cases this curve degenerates into a circle, a point, or an imaginary locus. [Art. 118, Nots]
(3) The hyperbola: neither $\boldsymbol{A}$ nor $\boldsymbol{B}$ is zero. and they have unlike signs. In exceptional eases this curve degenerates into a pair of real intersecting lines.
[Art. 119]
The ellipse and hyperbola have centers, and therefore are called central conics, while the parabola is said to be noncentral ; although it is at times more convenient to consider that the latter curve has a center at infinity, on the principil axis (cf. Appendix, Note E).

The equation for each conie has two standard forms, which state a characteristic geometric property of the curve and to which all other equations representing that species can be
reluced. These standard forms are the simplest for studying the curves; but the student must discriminate carefully between general results and those which hold only when the equation is in the standard form.
iv. tangents, normals, polars, diameters, etc.
121. Since the equation

$$
\begin{equation*}
A x^{2}+B y^{2}+2 G x+2 F y+C=0 \tag{1}
\end{equation*}
$$

always represents a conic whose axes are parallel to the coördinate axes, and since by giving suitable values to the constants $A, B, G, F$, and $C$, equation (1) may represent any such conic, therefore, if the equations of tangents, normals, polars, etc., to the locus of equation (1) can be found, independent of the values that $A, B$, etc., may have, these equations will represent the tangents, etc., when any special values whatever are given to the constants involved.

In the next few articles such equations will be derived.
122. Tangent to the conic

$$
A x^{2}+B y^{2}+2 G x+2 F y+C=0
$$

in terms of the coordinates of the point of contact: the secant method. The definition of a tangent has already been given (Art. 81), and the method to be employed here in finding its equation is the one which was used in Art. 84. That article should now be carefully re-read.

Let the given conic, i.e., the locus of the equation,

$$
\begin{equation*}
A x^{2}+B y^{2}+2 G x+2 F y+C=0 \tag{1}
\end{equation*}
$$

be represented by the curve $B H K$; and let $P_{1} \equiv\left(x_{1}, y_{1}\right)$ be the point of tangency.

Through $P_{1}=\left(x_{1}, y_{1}\right)$ draw a secant line L.M, and let $P_{8}=\left(x_{2} y_{c}\right)$ be its other point of intersection with the locus of equation (1). If the point $P_{2}$ moves along the curve until it comes inte coincidence with $P_{1}$, the limiting pesition of the secant $L M$ is the tangent $P_{1} T$.

The equation of the line $L M$ is

Fis. 90.

$$
\begin{equation*}
y-y_{1}=\frac{y_{2}-y_{1}}{x_{2}-x_{1}}\left(x-x_{1}\right) . \tag{2}
\end{equation*}
$$

If now $P_{2}$ approaches $P_{1}$ until $x_{2}=x_{1}$ and $y_{2}=y_{1}$, equation (2) assumes the indeterminate form

$$
\begin{equation*}
y-y_{1}=\frac{0}{0}\left(x-x_{1}\right) \tag{8}
\end{equation*}
$$

This indeterminateness arises because account has not yet been taken of the path (or direction) by which $P_{3}$ shall approach $P_{1}$, and it disappears immediately if the condition that $P_{1}$ and $P_{3}$ are points on the conic (1) is introdused. Since $P_{1}$ and $P_{2}$ are on the conic (1).
therefore $A x_{1}{ }^{2}+B y_{1}{ }^{2}+2 G x_{1}+2 F y_{1}+C=0$,
and

$$
\begin{equation*}
A x_{2}^{2}+B y_{2}^{2}+2 G x_{2}+2 F y_{2}+C=0 \tag{4}
\end{equation*}
$$

Sultracting equation (4) from equation (5), transposing, factoring, and rearranging [cf. Art. 84, equations (8), (9), and $(10)$ ], the result may be written

$$
\begin{equation*}
\frac{y_{2}-y_{1}}{x_{2}-x_{1}}=-\frac{A\left(x_{1}+x_{2}\right)+2 G}{B\left(y_{1}+y_{2}\right)+2 P} \tag{6}
\end{equation*}
$$

If this value of $\frac{y_{2}-y_{1}}{x_{2}-x_{1}}$ is substituted in equation (2), the result is

$$
\begin{equation*}
y-y_{1}=-\frac{A\left(x_{1}+x_{2}\right)+2 G}{B\left(y_{1}+y_{2}\right)+2 F}\left(x-x_{1}\right) \tag{i}
\end{equation*}
$$

which is the equation of the secant line $L M$ of the given conic (1).

If now this secant line be revolved about $P_{1}$ until $P_{3}$ comes into coincidence with $P_{1}$, i.e., until $x_{2}=x_{1}$ and $y_{2}=y_{1}$, this equation becomes

$$
\begin{equation*}
y-y_{1}=-\frac{A x_{1}+G}{B y_{1}+F}\left(x-x_{1}\right) ; \tag{8}
\end{equation*}
$$

which is, therefore, the equation of the tangent line $P_{1} T$ at the point $P_{1}$. This equation (8) can be put in a much simpler and more easily remembered form, thus :

Clearing equation (8) of fractions, and simplifying, it may be written
$A x_{1} x+B y_{1} y+G x+F y=A x_{1}{ }^{2}+B y_{1}{ }^{2}+G x_{1}+F y_{1} ;$
but, from equation (4),
$A x_{1}{ }^{2}+B y_{1}{ }^{2}+G x_{1}+F y_{1}=-G x_{1}-F y_{1}-C$,
hence substituting this value in the second member of equation (9) that equation becomes
$A x_{1} x+B y_{1} y+G x+F y=-G x_{1}-F y_{1}-C$,
and, by transposing and combining, this may be written,
$\boldsymbol{A} x_{1} \boldsymbol{x}+\boldsymbol{B} y_{1} y+\boldsymbol{G}\left(\boldsymbol{x}+\boldsymbol{x}_{1}\right)+\boldsymbol{F}\left(\boldsymbol{y}+\boldsymbol{y}_{1}\right)+\boldsymbol{C}=\mathbf{0}$.*
This is, then, the equation of the tangent to the conic

$$
A x^{2}+B y^{2}+2 G x+2 F y+C=0
$$

whatever the values of the coefficients $A, B, G, F$, and $C$ may be ; the point $\left(x_{1}, y_{1}\right)$ being the point of contact.

If $A=0, B=1, G=-2 p, F=0$ and $C=0$, then the equation of this conic becomes $y^{2}=4 p x$, and the equation of the tangent becomes, $y_{1} y=2 p\left(x+x_{1}\right)$; similarly for any other special form of the equation of the conic.

- Compare note, Art. 84, ( $\beta$ ).

123. Normal to the conic $A x^{2}+\boldsymbol{H} y^{2}+9 \boldsymbol{C} x+2 \boldsymbol{F} y+C=0$, at a given point. The sormal to a curve has brees defined (Art. 81) as a straight line perpendicular to a tangrat, and passing through the point of contact. Therefore, to obtain the equation of a normal to a conic, at a given print on the conic, it is only necessary to write the equation of the tangent to the conic at that point (hy Art. 122), and then find the equation of a perpendicular to the tangent which passes through the point of contact (cf. Arts. 53, 62).

Examples. To find the equation of the normal to the ellipse

$$
\frac{x^{2}}{18}+\frac{y^{2}}{8}=1
$$

at the point $(8,2)$.
The equation of the tangent at the point $(8,2)$ is

$$
\frac{8 x}{18}+\frac{2 y}{8}=1
$$

i.e.,

$$
2 x+3 y=12
$$

The perpendicular line through $(3,2)$ is

$$
3 x-2 y=5
$$

which is, therefore, the required normal.
Similarly, to find the normal to the conie whose equation is

$$
\begin{equation*}
A x^{2}+B y^{2}+2 G x+2 F y+G=0 \tag{1}
\end{equation*}
$$

at the point $P_{1} \equiv\left(x_{1}, y_{1}\right)$ on the curve. The equation of the tangent at $P_{1}$ is (Art. 122)
$A x_{1} x+B y_{1} y+G\left(x+x_{1}\right)+F\left(y+y_{1}\right)+C=0$
and its slope is, therefore, (Art. 58 (2))

$$
-\frac{A x_{1}+G}{B y_{1}+F}
$$

Hence the required equation of the corresponding normal at $P_{1}$ is (Arts. 53, 62)

$$
\begin{equation*}
y-y_{1}=\frac{B y_{1}+F}{A x_{1}+G}\left(x-x_{1}\right) . * \tag{51}
\end{equation*}
$$

## EXERCISES

1. Is the line $3 x+2 y=17$ tangent to the ellipse $16 x^{2}+25 y^{2}=400$ ?
2. Find the equation of a tangent to the conic $x^{2}+5 y^{2}-3 x+10 y$ $-4=0$, parallel to the line $y=3 x+7$ (cf. Art. 8?).

Write the equations of the tangent and normal to each of the follow: ing conics, through a point $\left(x_{1}, y_{1}\right)$ on the curve (cf. Art. 122 [50]).
3.

$$
\begin{aligned}
& \frac{x^{2}}{a^{2}}+\frac{y^{2}}{b^{2}}=1 \\
& \frac{x^{2}}{a^{2}}-\frac{y^{2}}{b^{2}}=1
\end{aligned}
$$

4. 
5. $x^{2}=4 p(y-5)$; sketch the figure.
6. $3 x^{2}-5 y^{2}+24 x=0$; sketch the figure.
7. $x^{2}+5 y^{2}-3 x+10 y-4=0$; sketch the figure.
8. Derive, by the secant method (cf. Art. 122), the tangent to the parabola $y^{2}=4 p x$; the point of contact being $\left(x_{1}, y_{1}\right)$.
9. Derive, by the secant method, the tangent to the ellipse $x^{2}+4 y^{2}$ $-8 x+20 y=0$; the point of contact being ( $x_{\mathrm{r}}, y_{1}$ ).

Write the equations of the tangents and normals to each of the following conies, at the given point : also sketch each figure:
10. $9 x^{2}+5 y^{2}+36 x+20 y+11=0$, at the point $(-2,1)$;
11. $9 x^{2}+4 y^{2}+6 x+4 y=0$, at the point ( 0.0 ) ;
12. $y^{2}-6 y-8 x=31$, at the point $(-3,-1)$;

[^34]13. $\frac{x^{2}}{4}+y^{2}=1$, at the point $(1, \sqrt{3})$;
14. $3 x^{8}+4 y^{3}=16$, at the proint $(2,-1)$.
124. Equation of a tangent, and of a normal, that pase through a given point which is not on the conic.

The method to be followed in finding the equation of a tangent, or of a nurmal, that passes through a given point which is not on the conie, may be illustrated by the following example; the same method in appllicable to asy conio whatever.

Let it tee required to find the equation of that tangent to the parabols

$$
\begin{equation*}
y^{2}-6 y-8 x-31=0 \tag{1}
\end{equation*}
$$

which passes through the point $(-1,-1)$. This point not being on the parabola, the methool of Art. 122 does not apply; but, assuming for the mument that it is prosible to draw such a tangent, let $\left(x_{1}, y_{1}\right)$ bo its point of contact. The equation of this tangent is (Art. 122)

$$
\begin{equation*}
y_{1} y-3\left(y+y_{1}\right)-4\left(x+x_{1}\right)-31=0 . \tag{2}
\end{equation*}
$$

Since this tangent passers through the print $(-1,-1)$, therefore eypar tion (2) is satistied by the coordinates -4 and -1 ,
i.e., $\quad-y_{1}-3\left(-1+y_{1}\right)-4\left(-1+x_{1}\right)-31=0$,
which reduces to

$$
\begin{equation*}
x_{1}+y_{1}+3=0 . \tag{3}
\end{equation*}
$$

Equation ( 4 ) furnishes one relation between the two unknown constants $x_{1}$ and $y_{1}$; another equation between these two unknowns is furmathed ly the fact that $\left(x_{1}, y_{1}\right)$ is a point on the paratrola ( 1 ) ; this equation is

$$
\begin{equation*}
y_{1}{ }^{3}-6 y_{1}-8 z_{1}-31=0 . \tag{5}
\end{equation*}
$$

Solving between equations ( 1 ) and ( 5 ) given

$$
x_{1}=-2 \pm 2 \sqrt{2} \text { and } y_{0}=-1 \mp 2 \sqrt{2}
$$

hence, there are teo points on the given parabola the tangents at which paom through the point $(-1,-1)$; their coordinates are $(-2+2 \sqrt{2}$, $-1-2 \sqrt{2})$ and $(-2-2 \sqrt{2},-1+2 \sqrt{2})$; and sutestituting either parr of these values for $x_{1}$ and $y_{1}$ in equation (2) gives the equation of a atraight line that is tangent to the parabola (1), and that pasess through the point $(-4,-1)$.

Sis, ton, if it is desired to find the equation of a normal through a pwint not on the curve it is only necessary to assume temporarily the coîn dinates of the promt on the curve through which this normal passes, and
then find these coördinates by solving two equations, corresponding to equations (4) and (5) above.

The problem of finding the above tangent could also have been solved by writing the equation of a line through the point $(-4,-1)$ (Art. 53) and having the undetermined slope $m$, and then so determining $m$ that the two points in which this line meets the parabola should be coincident.
125. Through a given external point two tangents to a conic can be drawn. This theorem can be proved in precisely the same way as the corresponding theorem in the case of the circle (Art. 89) was proved. It may also be proved by the method already applied to the parabola in the precerling article. Let the latter method be adopted. Suppose the equation of the conic to be

$$
\begin{equation*}
A x^{2}+B y^{2}+2 G x+2 F y+C=0 ; \ldots \tag{1}
\end{equation*}
$$

let the locus of this equation be represented by the curve $L P_{1} P_{2} L^{\prime}$, and let $Q \equiv(h, k)$ be the given external point.

$$
\text { If } P_{1} \equiv\left(x_{1}, y_{1}\right) \text { is a point }
$$

 on $L P_{1} P_{2} U$, then the equation of the tangent at $P_{1}$ is

$$
\begin{align*}
A x_{1} x & +B y_{1} y+G\left(x+x_{1}\right) \\
& +F\left(y+y_{1}\right)+C=0 \tag{2}
\end{align*}
$$

and this tangent will pass through the point $Q$ if

$$
\begin{align*}
A h x_{1} & +B k y_{1}+G\left(h+x_{1}\right) \\
& +F\left(k+y_{1}\right)+C=0 . \tag{3}
\end{align*}
$$

But $P_{1}$ being on the locus of equation (1), its coürdinates $x_{1}$ and $y_{1}$ also satisfy equation (1);

$$
\text { i.e., } \quad A x_{1}^{2}+B y_{1}^{2}+2 G x_{1}+2 F y_{1}+C=0 .
$$

If now equations (3) and (4) are solved for $x_{1}$ and $y_{1}$, two values of each are found; these values are both imaginary if $Q$ is within the conic, they are real but coincident if $Q$ is
on the conic, and they are real and distinct if $Q$ is outside of the conic. This juroves ant only the alove propmation but also the faet that no real tangent can be drawn to a conie through an internal point, and that only one tangent can he drawn to a conic through a given point on the curve.
126. Equation of a chord of contact. If the two tangents are drawn from an external point to a conic section, the straight line through the corresponding points of tangency is called the chord of contact correspunding to the print from which the tangents are drawn (ef. Art. 90).

Let $P_{1}=\left(x_{1}, y_{1}\right)$ be the external point from which the two tangents are ilrawn; $T_{2}=$
 $\left(x_{2}, y_{2}\right)$ and $T_{3}=\left(z_{3}, y_{3}\right)$, the points of tangency of these tangents to the conic whose equation is

$$
\begin{equation*}
A x^{2}+B y^{2}+2 G x+2 F y+C=0 ; \tag{1}
\end{equation*}
$$

it is required to find the equation of the line through $T_{2}$ and $T_{3}$.

The equation of the tangent at $T_{2}$ (cf. Art. 122) is

$$
\begin{equation*}
A x_{2} x+B y_{2} y+G\left(x+x_{3}\right)+F\left(y+y_{2}\right)+C=0, \ldots \tag{2}
\end{equation*}
$$

and the oquation of the tangent at $T_{8}$ is

$$
\begin{equation*}
A r_{8} x+B y_{3} y+G\left(x+r_{3}\right)+\boldsymbol{F}\left(y+y_{3}\right)+C=0 \ldots \tag{8}
\end{equation*}
$$

Since cach of these tangents, by hypothesis, passes through $P_{1}$, therefore the coördinates $x_{1}$ and $y_{1}$ satisfy both equation (2) and equation (8) ; i.o.,

$$
\begin{equation*}
A x_{1} x_{2}+B y_{1} y_{3}+G\left(x_{1}+x_{2}\right)+F\left(y_{1}+y_{2}\right)+C=0 \ldots \tag{4}
\end{equation*}
$$

and $A x_{1} x_{3}+B y_{1} y_{3}+C\left(x_{1}+x_{3}\right)+\boldsymbol{F}\left(y_{1}+y_{3}\right)+C=0$.

Equations (4) and (5), respectively, assert that the points

$$
\left.T_{2} \equiv x_{2}, y_{2}\right) \text { and } T_{8} \equiv\left(x_{8}, y_{8}\right)
$$

are each on the locus of the equation

$$
\begin{equation*}
A x_{1} x+B y_{1} y+G\left(x+x_{1}\right)+\boldsymbol{F}\left(y+y_{1}\right)+C=0 . \tag{52}
\end{equation*}
$$

But equation [52] is of the first degree in the two variables $x$ and $y$, hence (Art. 57) its locus is a straight line; i.e., [52] is the equation of the straight line through $T_{2}$ and $T_{3}$, which was to be found.

Note 1. The equation [52] of the chord of contact corresponding to a given external point $\left(x_{1}, y_{1}\right)$, and the equation [50] of the tangent whose point of contact is $\left(x_{1}, y_{1}\right)$ are identical in form. This might have been expected because the tangent is only a special case of the chord of contact, since the chord of contact, for a given point, approaches more and more nearly to coincidence with a tangent when the point is taken more and more nearly on the curve.

Note 2. The present article furnishes another method of treatment for the question of Art. 124. To get the equations of the two tangents that can be drawn through a given external point to a given conic, it is only necessary to write the equation of the chord of contact corresponding to this point; then find the points in which this chord of contact intersects the conic. These are the points of contact of the required tangents, whose equation may then be written down.

## EXERCISES

1. By first finding the chord of contact (Art. 126) of the tangents drawn from the point $\left(-\frac{1}{3}, \frac{13}{3}\right)$ to the conic

$$
4 x^{2}+y^{2}+24 x-2 y+17=0
$$

find the points of contact, and then write the equations of the tangents to the conic at these points; verify that these two tangents intersect in the point ( $-\frac{1}{2}, y_{3}^{2}$ ).
2. Solve Ex. 1 by the method of Art. 124.
3. Solve Ex. 1 by the method of Art. 83, using equation [11], p. 85.
4. Find the equation of a normal through the point $(7,5)$ to the conic

$$
-4 x^{2}+y^{2}+24 x-2 y+17=4
$$

Is it pronible to draw smore than one mormal through ( $\overline{0}$ is) tos the givees conle?
5. By the methomle of Exs. 1, 2, and 3, find the evpuations of the taugentas through the origin tes then conic

$$
8 x^{2}-2 y^{3}=6 x+8 y+6
$$

6. By the tumethonds of F.xs. 1, 2, and 3, find the equatoons of the tangents throught the proint $(-1,1)$ to the conic

$$
9 x^{2}+5 y^{2}+30 x+20 y+11=0 .
$$

7. Sketch the conies whose equations are given in Ex. 1, 5. and 6.
8. Find the equations of the tangents to the conic, $x^{2}+t y^{2}=\mathbf{t}$, from the point $(8,2)$.
9. Find the normals to the conic $x^{3}+4 y^{3}=4$, through the point $(1,0)$.
10. Solve Fxs. 8 and 8 , by assuming the slope $m$ of the reguired line (Art. 53), and then determining m so that the two pointe in which the line meets the given curve shall be coincident.
11. Poles and polars. If through any given point $P_{1}=\left(x_{1}, y_{1}\right)$, outside, inside, or on a given conic, a secant is drawn, meeting the conic in two points $Q$ and $R$, and if tangents at $Q$ and $R$ are drawn, they will intersect in some point, as $P^{\prime} \equiv\left(x^{\prime}, y^{\prime}\right)$. The locus of $P^{\prime}$ as the secant revolves about $P_{1}$ is the polar of the point $P_{1}$ (cf. Art. 91) with regard to the given conic; and $P_{1}$ is the pole of that locus.

To find the equation of the polar of a given point

$$
P_{1} \equiv\left(x_{1}, y_{1}\right)
$$

with regard to a given conic whose equation is

$$
\begin{align*}
A x^{2} & +B y^{2}+2 G x+2 F y \\
& +C=0 \tag{1}
\end{align*}
$$

let $Q P_{1} R$ be any position of she secant through $P_{v}$, and

let the tangents at $Q$ and $R$ intersect in $P^{\prime} \equiv\left(x^{\prime}, y^{\prime}\right)$. Then the equation of $Q P_{1} R$ (Art. 126) is

$$
\begin{equation*}
A x^{\prime} x+B y^{\prime} y+G\left(x+x^{\prime}\right)+F\left(y+y^{\prime}\right)+C=0 . \ldots \tag{2}
\end{equation*}
$$

Since this line passes through $P_{1}$, therefore the coördinates $x_{1}$ and $y_{1}$ satisfy equation (2),
i.e., $\quad A x_{1} x^{\prime}+B y_{1} y^{\prime}+G\left(x_{1}+x^{\prime}\right)+F\left(y_{1}+y^{\prime}\right)+C=0, \ldots$
and equation (3) asserts that the variable point $P^{\prime} \equiv\left(x^{\prime}, y^{\prime}\right)$ lies on the locus of the equation

$$
\begin{equation*}
A x_{1} x+B y_{1} y+G\left(x+x_{1}\right)+F\left(y+y_{1}\right)+C=0 \ldots \tag{4}
\end{equation*}
$$

Equation ( 4 ) is of the first degree in the variables $x$ and $y$, hence (Art. 57), its locus is a straight line; the polar of $P_{1}$, with regard to the conic (1), i.e., the locus of $P^{\prime}$, is then the straight line whose equation is

$$
A x_{1} x+B y_{1} y+G\left(x+x_{1}\right)+\boldsymbol{F}\left(y+y_{1}\right)+C=0 . \ldots[5: 3]
$$

Note. That the equation of a tangent [50] and of a chord of contact [ 52$]$ have the same form as equation [53] is due to the fact that a tangent, and a chord of contact, are but special cases of a polar.
128. Fundamental theorem. An important theorem concerning poles and polars is: If the polar of the point $P_{1}$, with

regard to a given conic, passes through the point $P_{2}$, then the polar of $P_{3}$ with regard to the same conic pasacs through $P_{1}$.

Let the equation of the given conic tre

$$
\begin{equation*}
A x^{3}+B y^{3}+2 G x+2 F y+C=0, \cdots \tag{1}
\end{equation*}
$$

and let the two given points be

$$
P_{1}=\left(x_{1}, y_{1}\right) \text { and } \boldsymbol{P}_{3} \equiv\left(x_{3}, y_{3}\right)
$$

Then the equation of the polar of $P_{1}$ with regard to the conic (1) is (Art. 127)

$$
A x_{1} x+B y_{1} y+G\left(x+x_{1}\right)+F\left(y+y_{1}\right)+C=0 ; \ldots(2)
$$

if this line passes through $P_{2}$, then

$$
A x_{2} r_{1}+B y_{2} y_{1}+\boldsymbol{F}\left(x_{2}+x_{1}\right)+\boldsymbol{F}^{\prime}\left(y_{2}+y_{1}\right)+C=0 \ldots \text { (3) }
$$

But the polar of $P_{2}$ with regard to the conic (1) is

$$
\begin{equation*}
A x_{2} x+B y_{2} y+G\left(x+x_{2}\right)+F\left(y+y_{2}\right)+C=0, \ldots \tag{4}
\end{equation*}
$$

and equation (3) shows that the loeus of equation (4) passes through the point $P_{1}$; which proves the proposition.
129. Diameter of a conic section. The locus of the middle points of any system of parallel chords of a given conic is called a diameter of that conic, and the chords which that diameter bisects are called the chords of that diameter.

For a given conic, it is required to find the equation of the diameter bisecting a system of chords whose slope is $m$. Let the equation of the given conic (H.JK, Fig. 96) be

$$
\begin{equation*}
A x^{2}+B y^{2}+2 G x+2 F y+C=0 \tag{1}
\end{equation*}
$$

let the equation of any one of the parallel chords of slope $m, L . M$ for example, be

$$
\begin{equation*}
y=m x+8_{1} \quad \bullet \cdot \bullet \cdot \tag{2}
\end{equation*}
$$

and let the two points in which it meets the given conic bo

$$
P_{1} \equiv\left(x_{1}, y_{1}\right) \text { and } P_{8} \equiv\left(x_{3}, y_{8}\right)
$$

Then (Art. 122, eq. (6)),

$$
\begin{equation*}
m=-\frac{A\left(x_{1}+x_{2}\right)+2 G}{B\left(y_{1}+y_{2}\right)+2 F} \tag{3}
\end{equation*}
$$

If $Q \equiv(h, k)$ be the middle point of the chord $P_{1} P_{2}$, then
$h=\frac{x_{1}+x_{2}}{2}$ and $k=\frac{y_{1}+y_{2}}{2}$;
substituting these values of $x_{1}+x_{2}$ and $y_{1}+y_{2}$ in equation (3), then clearing of fractions and transposing, that equation becomes

$$
\begin{equation*}
A h+m B k+G+m F=0 . \tag{4}
\end{equation*}
$$

But equation (t) asserts that the coördinates $(h, k)$ of the middle point of any one of this system of parallel chords satisfy the equation

$$
\begin{equation*}
A x+m B y+G+m \boldsymbol{F}=0 \tag{54}
\end{equation*}
$$

which is therefore the equation of the diameter whose chords have the slope $m$.

## EXERCISES

1. Find the polar of the point $(2,1)$ with regard to the hyperbols $x^{2}-2\left(y^{2}+x\right)-4=0$. Show that this polar passes through $(12,3)$, and then verify Art. 128, for this particular case, by showing that the polar of $(12,3)$, with regard to the given hyperbola, passes through $(2,1)$.
2. Write the equation of the chord of contact of the tangents drawn through $(2,1)$ to the hyperbola $x^{2}-2 y^{2}-2 x-4=0$, then find the points in which it meets the curve, get the equations of the tangents at these points, and verify that they pass through the given point $(2,1)$.
3. By specializing the coefficients in equation [54], prove that the diameter of a circle is perpendicular to the chords of that diameter.

Soletios. If equation (1) of ArL 123 reproments a circle, then $A=B$, and then equation [ [Si] levemen

$$
y=-\frac{1}{m} x-\frac{G+m F}{A m}
$$

i.e., the slope of the diameter is $-\frac{1}{m}$; but the slope of the given systers of chords is m, hence the diameter is perpendicular to its chords.
4. By means of eq. [54], i.e, by squecializing its coefficients, prove that the diameter of a circlo passes through the center of the circle.
5. By means of equation [34] prove that any diameter of the ellipme $3 x^{2}+y^{3}-6 x+2 y=0$ prases through the center of the ellipses. Does this property belong to all ellipses? To all conics?
6. Find the equation of that diameter of the hyperhols

$$
x^{2}-4 y^{2}+16 y+6 x-15=0
$$

whose chords are purallel to the line $y=2 x+10$. Does this diameter pass through the center of the curve?
7. Find the angle hetween the diameter and its chords in exercise 6.
8. Show that every diameter if the parabela $3 y^{2}-16 x+12 y=4$ is parallel to its axis. Is this a property belonging to all paraholas?
9. Derive, by the method of Art. 120, the equation of that diametor of the hypertmola $x^{3}-4 y^{2}+10 y+6 x-15=0$, which bisects chords parallel to the line $8 x-4 y=12$.
130. Equation of a conic that passes through the intersections of two given conics. Let the given conies bo

$$
\text { and } \quad \begin{align*}
& S_{1}=A_{1} x^{3}+B_{1} y^{2}+2 G_{1} x+2 F_{1} y+C_{1}=0, \ldots \text { (1) } \\
& S_{3}=A_{2} x^{2}+B_{2} y^{2}+2 G_{2} x+2 F_{2} y+C_{3}=0 ; \ldots \text { (2) }
\end{align*}
$$

then, if $k$ be any constant whatever,

$$
\begin{equation*}
S_{1}+k S_{2}=0 \tag{8}
\end{equation*}
$$

represents a conic whose axes are parallel to the colirdinate axes (Art. 120), and which passes through the points in which the conies $S_{1}=0$ and $S_{2}=0$ intersect each other (Art. 41) : i.e., $S_{1}+k S_{2}=0$ represents a family of conies, each member of which passes through the intersections of $S_{1}=0$ and $S_{2}=0$. The parameter $k$ may be so chosen that
the conic (3) shall, in addition to passing through the four points in which $S_{1}=0$ and $S_{2}=0$ intersect, satisfy one other condition ; e.g., that it shall pass through a given fifth point.

Moreover, if $S_{1}=0$ and $S_{2}=0$ are both circles, then $S_{1}+k S_{2}=0$ is also a circle (cf. Arts. $95^{\circ}$ and 96 ).

## v. polar kquation of the conic sections

131. Polar equation of the conic. Based upon the "focus and directrix" definition already given in Art. 48, the polar equation of a conic section is easily derived.

Let $D^{\prime} D$ (Fig. 97) be the given line (the directrix) and 0 the riven point (the focus); draw $Z O R$ through $O$ and per-
 pendicular to $D^{\prime} D$, and let $O$ be chosen as the pole and $O R$ as the initial line. Also let $P \equiv(\rho, \theta)$ be any point on the locus, and let $e$ be the eccentricity. Draw $M P$ and $O K$ parallel, and $L P$ and $H K$ perpendicular, to $D^{\prime} D$, and let $O K=l$; then

$$
\begin{aligned}
& O P=e \cdot L P,[\text { definition of the curve }] \\
= & e(Z O+O M) ; \\
\therefore \quad \rho= & e\left(\frac{l}{e}+\rho \cos \theta\right) .
\end{aligned}
$$

This equation, when solved for $\rho$, may be written in the form

$$
\begin{equation*}
p=\frac{l}{1-\theta \cos \theta}, \tag{55}
\end{equation*}
$$

which is the polar equation of a conic section referred to its focus and principal axis; $e$ being the eccentricity and $l$ the semi-latus-rectum. If $e=1$, equation [55] represents a parabola; if $e<1$, an ellipse ; and if $e>1$, an hyperbola.

Note. Equation $[85]$ shown that if $e<1$ i, ie., it the equatimas rapine nets an ellipses, there is me value of $\theta$ for whirls $\rho$ leones infinite. Therefore there in no direction in which a line may be draw is to meet an ellipse ut inanity. If $e=1$, ie., if the equation represents a parabolas there is ce value of $\theta$, viz. $\theta=0$, for which $p$ becomes infinite. There fore there is one direction in which a line may le drawn to meet a pratcts at infinity. If ep, ie., if the equation represents an hyperbolas. there are two values of $\theta$. viz., $\theta \equiv \pm \cos ^{-1}(1 ; e)$, for which $\rho$ becomes infinite. Therefore there are tire directions ia which a line may be drawn to meet an hyperbola at infinity.

The threes species of conic sections may therefore be distinguished from each other by the number of directions in which lines may le drawn through the foens to meet the curve at infinity. Or, since parallel lines moet at infinity, any point of the plane may to used instead of the focus.
132. From the polar equation of a conic to trace the curve. Suppose $e>1$, ie., suppose equation [ 30 ] represents an hyperbola. When $\theta=0$, $\rho=\frac{1}{1-e}$, hence $\rho$ is negative; as $\theta$ increases, $\cos \theta$ decreases, and $e \cos \theta$ becomes numerically more and more nearly equal to 1 ; therefore $\rho$ remains negative and beemmer larger and larger;
$p=-\infty$ when

$$
1-e \cos \theta=0,
$$

ie., when

$$
\theta=\cos ^{-1}\left(\frac{1}{e}\right)=a
$$

say; as 0 increases through this value, $\rho$ becomes $+\infty$ and then decreases, hut remains [motive, and becomes

Fro. 8.
coal to $l$ when $\theta=90^{\circ}$; as $\theta$ increases through mo to $180^{\circ}, \rho$ remains positive, hut continues to decrease, reaching its smallest value, viz $\rho=\frac{1}{1+e}$, when $\theta=180^{\circ}$; as $\theta$ increases from $180^{\circ}$ to $270^{\circ}, \rho$ remains pwitive and increases from $\frac{1}{1+0}$ to $l$; an $\theta$ increases from $270^{\circ}$ to $36 \operatorname{lil}^{\circ}-\alpha, \rho$ increases from $l$ to $+\infty$; as $\theta$ increases through $360^{\circ}-a, p$ becomes - $-\infty$; and finally, as $\theta$ increases from $380^{\circ}$ - a to $300^{\circ}, p$ m mains negative, hut demenawes numerically, reaching the value $\frac{1}{1-0}$ again when $\theta$ becomes $360^{\circ}$.

These deductions from equation [55] show that the hyperbola has the form represented in Fig. 9s, and that, as $\theta$ increases from 0 to $a$, the lower half $A^{\prime} W$ of the infinite branch at the left is traced; as $\theta$ increases from a to $300^{\circ}$ - a the right hand branch $V A U$ is traced; and as $\theta$ increases from $360^{\circ}-a$ to $360^{\circ}$, the upper half $S A^{\prime}$ of the left hand branch is traced.

If $\theta$ increases beyond $360^{\circ}$, the tracing point moves along the same curve; this is also true if $\theta$ changes from $0^{\circ}$ to $-360^{\circ}$.

Note. To show the identity of the curve as traced in the present article and in Art. 117, it need only be recalled that

$$
e=\frac{\sqrt{a^{2}+b^{2}}}{a} \text {, and that } l=\frac{b^{2}}{a} \text {. }
$$

These values substituted above show that

$$
a=\cos ^{-1}\left(\frac{a}{\sqrt{a^{2}+b^{2}}}\right)=\tan ^{-1}\left(\frac{b}{a}\right) \text {, that } O A=-\left(a+\sqrt{a^{2}+b^{2}}\right) \text {, etc. }
$$

## EXERCISES

1. From equation [55], trace the parabola.
2. From equation [55], trace the ellipse.
3. By means of equation [55], prove that the length of a chord through the focus of a parabola, and making an angle of $30^{\circ}$ with the axis of the curve, is four times the length of the latus-rectum.
4. By transforming from rectangular to polar coördinates, derive the polar equations of the conic sections from their rectangular equations.

## EXAMPLES ON CHAPTER VIII

1. Find the equations of those tangents to the conic $9 x^{2}-16 y^{2}=144$, which pass through the point $(0,1)$.
2. What is the polar of the point $(7,2)$ with reference to the conio $16 y^{2}+9 x^{2}=144$ ? Find the equation of the line which is tangent to the conic and parallel to this polar.
3. Find the polars of the foci of the ellipse $\frac{x^{2}}{9}+\frac{y^{2}}{16}=1$, with regard to this ellipse. Also for the parabola $y^{2}=4 p x$.
4. What is the equation of the polar of the center of the conic $A x^{2}+B y^{2}+2 G x+2 F y+C=0$, with reference to the conic?
5. What is the pole of the directrix of the hyperbola $x^{2}-4 y^{2}=16$, with reference to that curve?
6. The line $y=m(x-u e)$ prasses throught the focus of thes onntral conic $\frac{a^{2}}{\mathrm{c}^{2}} d \frac{y^{2}}{p^{2}}=1$. On what line dows its pole lie? Find the line foinsing its pule to the focus. What relation exists between this line and the given focal chord?
7. What is the polar of the vertex of the comie

$$
A x^{3}+B y^{3}+2 G x+2 F y+C=0
$$

with reference to the curve?
a. What is the equation of each common chard of the two conies

$$
16 x^{2}+9 y^{2}=141, \quad 16 x^{2}-9 y^{2}=144 ?
$$

Hist. Tse Art. 133, equation 3; find if wo that $S_{1}+1 S_{2}$ can be factared.
9. Prove that the perpemdicular dropped from any point of the directrix, to the polar of that point, passes through the focus

$$
\text { (a) for } y^{2}=4 \text { pr. ( } \beta \text { ) for } \frac{x^{2}}{a^{2}} \pm \frac{y^{2}}{b^{2}}=1 \text {. }
$$

Viing the simplest standard equations of the conien, find for each
10. the polar of the focus;
11. the pole of the directrix;
12. the pole of each axis; and, for the ellipse and hyperbola, the polar of the conter.
13. Find a conie through the intersections of the ellipese $4 x^{2}+y^{3}-16$ and the parabola $y^{2}=4 x+4$, and also prassing througt the point 2,2 . What kind of a conic is it ?
14. Show that the curves $\frac{x^{3}}{10}+\frac{y^{3}}{7}=1$ and $\frac{x^{2}}{4}-\frac{y^{3}}{5}=1$ have the same foci, and that they cut each other at right angles.
15. Find the vertices of an equilateral triangle cireumseriled alvont the ellipse $9 x^{3}+16 y^{2}=14$, one side being parallel to the major axis of the curve.
16. Find the normal to the conic $3 x^{2}+y^{3}-2 x-y=\hat{1}$, making the angle $\tan ^{-1}\left(\frac{\xi}{}\right)$ with the $x$-axis.
17. Show that the locus of the pole, with respect to the parabola $y^{2}=4 a x$, of a tangent to the hyperbola $x^{8}-y^{3}=a^{3}$, is the cllipse $\left\{x^{4}+y^{8}=4 a^{8}\right.$.
18. Show that $\frac{x^{2}}{a^{2}-1^{4}}+\frac{y^{2}}{b^{2}-1^{3}}=1$, where $t$ is an arlitrary cons stant, represents an ellipse having the same foel as $\frac{b^{b}}{a^{b}}+\frac{y^{2}}{b^{2}}=1$ when
$k^{3}<b^{2}$; but represents a confocal hyperbola when $a^{2}>k^{2}>b^{2}$; given $a>b$.

Determine the nature of the followin: conics; and also their foci, directrices, centers, semi-axes, and latera recta:
19. $y^{2}=(x+3)(x+4)$;
20. $x^{2}-4 y^{2}+x+y+1=0$;
21. $x^{2}=4 x+11 y+7$;
22. $3 x^{2}+y^{2}-6 x+8 y+1=0$;
23. $3 x^{2}+5 y=3 y^{2}+5 x$;
24. $9\left(x^{2}-y\right)=3 y(1+2 x-3 y)$.
25. Show that the polar equation of the parabola, with its vertex at the pole, is $\rho=\frac{4 p \cos \theta}{\sin ^{2} \theta}$.
26. Show that if the left hand focus be taken as pole, the polar equation of the ellipse is $\rho=\frac{a\left(1-e^{2}\right)}{1-e \cos \theta}$.
27. Derive the polar equation of an hyperbola, with its pole at the focus, eccentricity 2, and the distance of the focus from the directrix squal to 6.

## CHAPTER IX

## THE PARABOLA $y^{2}=4 p x$

133. Review. In the preceding chapter (Arts. 102 to 108), tie nature of the parabola has been examined, and its equation derived in two standard forms. These equations are :
$y^{3}=4 j x$, if the axis of the curve coincides with the $x$-axis, and the tangent at the vertex with the $y$-axis; and
$(y-k)^{2}=4 p(x-h)$, if the axis of the curve is parallel to the $x$-axis, and the vertex is at the point $(h, k)$. In the present chapter, some of the intrinsie properties of the parabola are to be stulied, i.e., properties which belong to the curve and are entirely independent of the position of the courdinate axes. For this purpose, it will, in general, be easier to use the simplest form of the equation of the curre, viz., $y^{2}=4 p x$.

In every parabola, the value of the eecentricity is $e=1$. If the equation of the parabola is $y^{3}=4 p x$, then the focus is the point $(p, 0)$, the directrix is the line $x=-p$, and the axis of the curve is the line $y=0$. The equation

$$
y_{1} y=2 p\left(x+x_{1}\right)
$$

represents the polar of the point $P_{1} \equiv\left(x_{1}, y_{1}\right)$ with respect to the parabola, for all positions of $\boldsymbol{P}_{\mathbf{1}}$. If $\boldsymbol{P}_{1}$ be outsite the curve, this polar is the chord of contact corresponding to tangents from $P_{1}$; if $P_{1}$ bo upon the eurve, this prolar is the tangent at that point. These facts, shown in the
previous chapter, will be assumed in the following discussion.
134. Construction of the parabola. The two conceptions of a locus given in Article 35 lead to two methods for constructing a curve, viz., by plotting points to be connected by a smooth curve, and by the motion of a point constrained by some mechanical device to satisfy the law which defines the curve. These two methods may be used in constructing a parabola.
(a) By separate points. Given the focus $F$ and the vertex $O$, draw the axis $O F X$, the directrix $D^{\prime} D$ cutting this axis
 in $Z$, and also a series of lines perpendicular to the axis at $M_{1}, M_{2}, M_{3}$, etc., respectively. With $F$ as center and $Z M_{1}$ as radius, describe ares cutting the line at $M_{1}$ in two points $P_{1}$ and $Q_{1}$; similarly, with $F$ as center and $Z M_{2}$ as radius, cut the line at $M_{2}$ in $P_{2}$ and $Q_{2}$; and so on. The points thus found evidently satisfy the definition of the parabola (Art. 102). In this way, as many points of the curve as are desired may be found. If these be then connected by a smooth curve, it will be approximately the required parabola (cf. Note B, Appendix).
( $\beta$ ) By a continuously moving point. Let $D^{\prime} D$ be the directrix and $F$ the focus. Place a right triangle with its longer side $K I I$ in coincidence with the axis of the curve, and its shorter side $K J$ in coincidence with the directrix. Let one end of a string of length $K H$ be fastened at
$I I$, and the other end at $F$. If now a pencil point be pressed against the string. keeping it taut while the triangle is moved along the directrix, as indicated in the figure, then, in every position of $P$.

$$
F P=K P
$$

therefore the pencil will trace an are of a parabola.

135. The equation of the tangent to the parabola $\boldsymbol{v}^{2}=4 p x$ in terms of its slope. The equation of a line having the given slope $m$ is

$$
\begin{equation*}
y=m x+k ; \tag{1}
\end{equation*}
$$

it is desired to find that value of $k$ for which this line will Inecome tangent to the parabola whose equation is

$$
\begin{equation*}
y^{2}=4 p x \tag{2}
\end{equation*}
$$

Considering equations (1) and (2) as simultaneons, and eliminating $y$, the resulting equation, which is

$$
\begin{equation*}
(m x+k)^{2}=4 p x \tag{3}
\end{equation*}
$$

has for its roots the abscissas of the two points in which the loci of equations (1) and (2) intersect. These roots will trecome equal (ef. Art. 9), and therefore the points of intersection will lxecome coincident, if

$$
(m k-2 p)^{2}-m^{2} k^{3}=0
$$

i.e., if

$$
\begin{equation*}
k \circ \frac{p}{m} \tag{4}
\end{equation*}
$$

Therefore

$$
y=m x+\begin{gather*}
p  \tag{66}\\
m
\end{gather*}
$$

is, for all values of $m$, the equation of a tangent to the parabola

$$
y^{3}=4 p x
$$

The abscissa of the point of contact of the loci of equations (2) and [56] may be found from equation (3), by sub. stituting in it the value of $k$ given in equation (4); it is $\frac{p}{m^{2}}$. The ordinate may then be found from equation (1); it is $\frac{2 p}{m}$. The point of contact is then $\left(\frac{p}{m^{2}}, \frac{2 p}{m}\right)$.
136. The equation of the normal to the parabola $y^{2}=4 p x$ in terms of its slope. Since, by definition, the normal to a curve is perpendicular to the tangent at the point of contact, the equation of a normal to the parabola

$$
\begin{equation*}
y^{2}=4 p x \tag{1}
\end{equation*}
$$

is, if $m^{\prime}$ be the slope of the tangent [Arts. 62, 135],

$$
\begin{equation*}
\left(y-\frac{2 p}{m^{\prime}}\right)=-\frac{1}{m^{\prime}}\left(x-\frac{p}{m^{\prime 2}}\right) \tag{2}
\end{equation*}
$$

If $m$ be the slope of the normal, then

$$
m=-\frac{1}{m}
$$

and equation (2) may be written

$$
\begin{equation*}
y=m x-2 p m-p m^{3} \tag{57}
\end{equation*}
$$

This is the equation of a normal in terms of its own slope $m$.

137. Subtangent and subnormal. Construction of tangent and normal. Let $P_{1} \equiv\left(x_{1}, y_{1}\right) \quad$ be any given point on the parabola whose equation is

$$
y^{2}=4 p x \ldots(1)
$$

Draw the ordinate $M P_{1}$, the tangent $T P_{1}$. and the normal $P_{1} N$.

Then by the definitions of Art . 86 , the subtangent is $T M$, the subnormal is $M N$, the tangent length $T P_{1}$, and the normal length $P_{1} N$. The tangent at $P_{1}$ has for its equation (Art. 12\%),

$$
\begin{equation*}
y_{1} y=2 p\left(x+x_{1}\right), \tag{2}
\end{equation*}
$$

hence its $x$-intercept is $A T=-x_{1}$. But $A M=x_{1}$, therefore

$$
T M=2 x_{1} .
$$

This proves that the subtangent of the parabola $y^{2}=4 p x$ is bisected at the verter; and that its length is equal to twice the abscisad of the point of contact.

The normal at $P_{1}$ has for its equation (Art. 123)

$$
\begin{equation*}
y-y_{1}=-\frac{y_{1}}{2 p}\left(x-x_{1}\right) \tag{3}
\end{equation*}
$$

hence its $x$-intereept is $A N=x_{1}+2 p$. But $A M=x_{1}$, cherefore

$$
M N=2 p
$$

That is, in words, the sulonormal of the parabola $y^{2}=4 p x$ is constant; it is equal to half the latus rectum.

These properties of the subtangent and "subnormal give two simple methods of constructing the tangent and normal to any parabola at a given point, if the axis of the parabola is given.

First method : from the given point, let fall a perpendicnlar $P_{1}, M$ to the axis of the parabola, meeting it in $M$. The vertex of the curve being at $A$, construct the point $T$ on the axis produced, so that $T A=A M$. The straight line $T P_{1}$ is the required tangent at $P_{1}$, and a line through $P_{1}$ at right angles to this tangent is the required normal.

Second methol. from the foot of the perpendicular $M P_{1}$ construct the point $\boldsymbol{N}$, so that $M . V$ equals twice the distance from vertex to the focus $(2 p=2 A F)$; then $P_{1} N$ is the required normal, and a line through $\boldsymbol{P}_{1}$ at right angles to $P_{1} V$ is the required tangent.

## EXERCISES

1. Construct a parabola with focus 2 mm from the directrix.
2. Construct a parabola with latus rectum equal to 6 .
3. Find the equations of the two tangents to the parabola $y^{2}=4 p x$, which form with the tangent at the vertex a circumscribed equilateral triangle. Find also the ratio of the area of this triangle to the area of the triangle whose vertices are the points of tangency.
4. Find the equation of a tangent to the parabola $y^{2}=4 p x$, perpendicular to the line $4 y-x+3=0$, and find its point of contact.
5. Find the equations of the two tangents to the parabola $y^{2}=5 x$ from the point ( $-1,1$ ), using formula [56].
6. Write the equations of the tangents to the parabola $y^{2}=10 x$, at the extremities of the latus rectum. On what line do these tangents intersect? (cf. Art. 138 (5), p. 228.)
7. Write the equations of the tangent and normal to the parabola $y^{2}=9 x$, at the point $(4,6)$.
8. Write the equation of the normal to the parabola $y^{2}=6 x$, drawn through the point $\left(\frac{1}{2}, 3\right)$.
9. Write the equation of the tangent to the parabola $y^{2}=4 p x$, for the point for which the normal length equals $t$ wice the tangent; for the point for which the normal length is equal to the difference between the subtangent aud subnormal.
10. Two equal parabolas have the same vertex, and their axes are at right angles; find the equation of their common tangent, and show that the points of contact are each at the extremity of a latus rectum.
11. Find the locus of the middle point of the normal length of the parabola $y^{2}=4 p x$.
12. The subtangent of a parahola for the point ( 5,4 ) is 10 ; find the equation of the curve, and length of the subnormal.
13. Find the subtangent, and the normal length, for the point whose alscissa $=-6$, and which is on the parabola $y^{2}=-6 x$.
14. Find the equation of the tangent parallel to the polar of $(-1,2)$ with respect to the parabola $y^{2}=12 x$; also find the point of contact, the length of the tangent, and the subtangent.
15. Find the equation of a parabola which is tangent to $2 y-3 x=1$, whose vertex is at the origin, and whose axis is parallel to the $x$-axis.
16. Show that the sum of the sulthangent and subhormal for auy point on the parabola $y^{0}=1$ ps, equals one hatf the length of focal chord prarallel to the corresponding tangent.
17. Show that an the alserissa in the parabola $y^{3}=4 \beta x$ increanes from 0 to ac, the absolnte value of the sloper of the tangent chauges from s to 0 ; bence the curve is concave towaril its axis.
18. Some properties of the parabola which involve tangents and normals. Let $F$ be the focus, $A$ the vertex, $A X$ the

axis, and $D / D$ the directrix of the parabola whose equation is

$$
\begin{equation*}
y^{3}=4 p x \tag{1}
\end{equation*}
$$

Through any point $P_{1} \equiv\left(x_{1}, y_{1}\right)$ on the curve draw the tangent $T P_{1}$, catting the $y$-axis in $R$, the directrix in $S$, and the $x$-axis in $T$; also draw the normal $P_{1} N$; the focal chord $P_{2} F P_{1}$; the tangent at $P_{2}$; the limes $L_{1} P_{1} Q$ and $L_{2} P_{2}$. per${ }^{2}$ wonlicular to the directrix; and the lines $S F$ and $L_{1} F$. Then the following properties of the parabola are readily obtained :
(1) The foeus is equidistant from the points $P_{1}, T$, and $N$.

For

$$
\begin{array}{rlrl}
F P_{1} & =L_{1} P_{1}=Z A+A M_{1}=x_{1}+p, \\
T F & =T A+A F=x_{1}+p, & \text { Art. } 137 \\
F N & =A M_{1}+\left(M_{1} N-A F\right)=x_{1}+p ; & \text { Art. } 137 \\
F P_{1} & =T F=F N .
\end{array}
$$

and
hence
The point $F$ is the midpoint of the hypotenuse of the right triangle $T P_{1} N$, and is therefore equidistant from the vertices $T, P_{1}$, and $N$. Thus a third method is suggested for constructing the tangent and normal at $P_{1}$, viz.: by means of a circle, with the focus $F$ as center, and the focal radius $F P_{1}$ as radius, which cuts the axis in $T$ and $N$.
(2) The tangent and normal bisect internally and externally, respectively, the angle between the focal radius to the point of contact and the perpendicular from that point to the directrix.

For $\quad \angle L_{1} P_{1} T=\angle P_{1} T F$, since $L_{1} P_{1} \| T F$;
and

$$
\angle T P_{1} F=\angle P_{1} T F, \text { since } T F=F P_{1}
$$

$\therefore \quad \angle L_{1} P_{1} T=\angle T P_{1} F$.
Also, $\quad \angle F P_{1} N=\angle N P_{1} Q$, since $P_{1} N \perp P_{1} T$.
(3) Through any point in the plane tuo tangents can be drawn to the parabola (ef. Arts. 89, 125).

The line

$$
\begin{equation*}
y=m x+\frac{p}{m} \tag{1}
\end{equation*}
$$

is tangent to the parabola $y^{2}=4 p x$ for all values of $m$. If $P^{\prime} \equiv\left(x^{\prime}, y^{\prime}\right)$ be any given point of the plane, then the tangent (1) will pass through $P^{\prime}$ if, and only if, $m$ satisfy the equation

$$
y^{\prime}=m x^{\prime}+\frac{p}{m}
$$

i.e., if

$$
\begin{equation*}
m=\frac{y^{\prime} \pm \sqrt{y^{\prime 2}-4 p x^{\prime}}}{2 x^{\prime}} . \tag{2}
\end{equation*}
$$

Therefore two, and only two, values of $m$ satisfy the given conditions; and therefore through any point of the plane two
tangents can the drawn to the parabola. If, however, $P$ is on the curve, then $y^{\prime 2}-4 p x^{\prime}=0$, the two values of $m$ are equal, i.e., the two tangents coincide. If $P^{\prime}$ is inside the parabola, then $y^{\prime 2}-4 p x^{\prime}<0$, and the two values of $m$ are imaginary, i.e., there are no real tangent lines. Therefore it is only when $I^{\prime \prime}$ is outside the parabola that two real and different tangent lines may be drawn from it to the parabola.
(4) Through any point in the plane three normals aun be drasm to the parabola.

The line

$$
\begin{equation*}
y=m x-2 p m-p m^{3} \tag{1}
\end{equation*}
$$

is normal to the parabola $y^{2}=4 p x$ for all values of $m$ (Art. 136). If $P^{\prime} \equiv\left(x^{\prime}, y^{\prime}\right)$ be any point of the plane, then the normal (1) will pass through $P^{\prime}$ if, and only if, $m$ has a value that will satisfy the equation

$$
\begin{equation*}
y^{\prime}=x^{\prime} m-2 p m-p m^{3} \tag{2}
\end{equation*}
$$

Since equation (2) is a cubic in $m$, there are three values of $m$ which satisfy the given conditions, and therefore, in general, three normals may be drawn to a parabola from a given point. Special cases may, however, arise in which two of the roots of equation (2) are equal, when there would be only two different normal lines; or all the roots may be equal, * or two imaginary and one real, in both of which cases there wonld the only one normal line. Through every point at least one normal line can be drawn to the parabola.
(i) The tangents at the extremities of a focal chord intersed on the directrir, and at right angles (cf. (6), below).

For, if $S \equiv\left(x^{2}, y^{\prime}\right)$ is the point of intersection of the tangents at the extremities of the focal chord, then the choml is the polar of $S$, and its equation is

$$
\begin{equation*}
y^{\prime} y=2 p\left(x+x^{\prime}\right) \tag{1}
\end{equation*}
$$

[^35]But since this line passes through the focus $F \equiv(p, 0)$,
$\therefore \quad 0=2 p\left(p+x^{\prime}\right)$;
i.e., $x^{\prime}=-p$. . .

Hence the point $P^{\prime}$ is on the locus $x=-p, i . e$., on the directrix.

Again, the tangent line

$$
\begin{equation*}
y=m x+\frac{p}{m} \tag{8}
\end{equation*}
$$

passes tirough the point $P^{\prime} \equiv\left(-p, y^{\prime}\right)$
if

$$
y^{\prime}=-m p+\frac{p}{m}
$$

i.e., if

$$
\begin{equation*}
m^{2}+\frac{y^{\prime}}{p} m-1=0 \tag{4}
\end{equation*}
$$

But the roots of equation (4) are the slopes $m^{\prime}$ and $m^{\prime \prime}$ of the two tangents at $P_{1}$ and $P_{2}$; and by Art. 11,

$$
m^{\prime} m^{\prime \prime}=-1
$$

Hence, the tangents at $P_{1}$ and $P_{2}$ intersect at right angles.
(6) The line joining any point in the directrix to the focus of a parabola is perpendicular to the chord of contact corresponding to that point.

For

$$
\triangle S L_{1} P_{1}=\triangle S F P_{1}
$$

since $\quad L_{1} P_{1}=F P_{1}, S P_{1}$ is common, $\angle L_{1} P_{1} S=\angle S P_{1} F_{\text {; }}$;
hence, $\quad \angle S F P_{1}=\angle S L_{1} P_{1}=90^{\circ}$.
The property of (5) may now be shown geometrically. Draw the tangent at $P_{2}$, and suppose it to meet the directrix in $S^{\prime \prime}$; then, by what has just been proved, $\angle S^{\prime \prime} F P_{2}$ is a right angle; then $F S^{\prime}$ must coincide with $F S^{\prime}$; and the tangents at $P_{1}$ and $P_{2}$ meet on the directrix.

Moreover, $\angle P S P_{1}$ is a right angle, for $S P$. bisectis $\angle F S L_{1}$, and $S P_{2}$ lisects $\angle L_{2} S F$.
(i) A perpendivular let fall from the focus upun a cannene line mects that tangent upon the tangent at the vertex.

For the equation of the tangent at $P_{1}$ is

$$
\begin{equation*}
y_{1} y=2 p x+2 p x_{1} \tag{1}
\end{equation*}
$$

and the equation of the perpendicular through the focus $F=(p, 0)$ is

$$
\begin{equation*}
2 p y=-y_{1} x+p y_{1} . \tag{2}
\end{equation*}
$$

liogarding equations (1) and (2) as simultaneous, and solving to find the point of intersection $\boldsymbol{R}$, its abscisse is determined by the equation

$$
\left(4 p^{2}+y_{1}{ }^{2}\right) x+p\left(4 p x_{1}-y_{1}{ }^{2}\right)=0 ;
$$

or, since

$$
\begin{align*}
y_{1}{ }^{2} & =4 p x_{10} \\
x & =0 \tag{8}
\end{align*}
$$

and $R$ is therefore on the tangent at $A$.
Nurg. The preceding properties of the parabola have for variety tween given in some cases a geometric, in others an analytic, proof. The student is advised to use thoth methods of proof for each propmition. Other properties of the parabola are given below as exerecses for the student, and should be derived by analytie methouls.

## EXERCISES

1. Write the equations of the nermals drawn through the point $(3,3)$ to the parabola $y^{3}=6 x$.
2. The focal distance of any point of the proraluola $y^{3}=4 p r$ is $p+x$
3. The circle on a focal chord as diameter touches the directris.
4. The angle between two tangents to a parabola is one half the angle between the fowal radii of the pwints of tangency:
5. The polars of all points on the latus rectum meet the axis of the parabola in the same point; find its coördinates, for the parabola $y^{2}=4 p x$.
6. The product of the segments of any focal chord of the parabola $y^{2}=4 p x$ equals $p$ times the length of the chord.
7. Two tangents are drawn from an external point $P_{1} \equiv\left(x_{1}, y_{1}\right)$ to a parabola, and a third is drawn parallel to their chord of contact. The intersection of the third with each of the other two is half way between $\boldsymbol{P}_{1}$ and the corresponding point of contact.
8. The area of a triangle formed by three tangents to a parabola is one half the area of the triangle formed by the three points of tangency.
9. The tangent at any point of the parabola will meet the directrix and latus rectum produced, in two points equidistant from the focus.
10. The normal at one extremity of the latus rectum of a parabola is parallel to the tangent at the other extremity.
11. The tangents at the ends of the latus rectum are twice as far from the focus as they are from the vertex.
12. The circle on any focal radius as diameter touches the tangent drawn at the vertex of the parabola.
13. The line joining the focus to the pole of a chord bisects the angle subtended at the focus by the chord.
14. Prove, geometrically, that a perpendicular let fall from the focus upon a tangent line of a parabola meets that tangent upon the tangent drawn at the vertex (cf. (7) of Art. 138, p. 229).
15. Diameters. A dianeter has been defined as the locus of the middle points of a system of parallel chords. Its equation may be found as follows (cf. Art. 129):

Let $m$ be the common slope of a system of parallel chords of the parabola whose equation is

$$
\begin{equation*}
y^{2}=4 p x, \tag{1}
\end{equation*}
$$

then the equation of one of these chords is

$$
\begin{equation*}
y=m x+k \tag{2}
\end{equation*}
$$

and the equation of any other chord of the system will differ from this only in the value of the constant term $k$. The chord (2) meeta the parabola (1) in two points

$$
P_{1}=\left(x_{1}, y_{1}\right)
$$

and $P_{9}=\left(x_{2}, y_{2}\right)$, and the coorrdinates of the middle point $p^{\prime} \equiv\left(x^{\prime}, y^{\prime}\right)$ are therefore

$$
\begin{equation*}
x^{\prime}=\frac{x_{1}+x_{2}}{2} \text { and } y^{\prime}=\frac{y_{1}+y_{2}}{2} \tag{3}
\end{equation*}
$$

Considering (1) and (2) as simultaneous equations, and eliminating $x_{\text {, }}$ it follows that the ordinates of $\boldsymbol{P}_{1}$ and $\boldsymbol{P}_{\mathbf{3}}$ are the roots of the equation
i.e., of

$$
\begin{gather*}
m y^{2}=4 p(y-k) \\
y^{2}-\frac{4 p}{m} y+\frac{4 p k}{m}=0 \tag{4}
\end{gather*}
$$

Therefore, by Art. 11,

$$
y_{1}+y_{2}=\frac{4 p}{m}, \text { i.e., } y^{\prime}=\frac{2 p}{m}
$$

hence whatever the value of $k$, the courdinates of the middle point of the chord satisfy the equation

$$
\begin{equation*}
y=\frac{2 p}{m} \tag{5}
\end{equation*}
$$

This is, therefore, the equation of the diameter corresponding to the system of chords whose slope is $m$.*

[^36]140. Some properties of the parabola involving diameters. The equation of the diameter of the parabola (Art. 139),
\[

$$
\begin{equation*}
y=\frac{2 p}{m} \tag{1}
\end{equation*}
$$

\]

shows at once that every diameter of the parabola is parallel to the axis of the curve. (See also Ex. 8, p. 213.)

Conversely, since any value whatever may be assigned to $m$, each value determining a system of parallel chords, equation (1) may represent any line parallel to the $x$-axis, and therefore every line parallel to the axis of a parabola bisects some set of parallel chords, and is a diameter of the curve.

Again, each of the chords cuts the parabola in general in two distinct points, and the nearer these chords are to the extremity of the diameter the nearer are these two points to each other and to their mid-point. In the limiting position, when the chord passes through the extremity of the diameter, the two intersection points and their mid-point become coincident, and the chord is a tangent. Therefore the tangent at the end of a diameter is parallel to the lisected chords.

It follows from the preceding properties, or directly from equation (1), that the axis of the parabola is the only diameter perpendicular to the tangent at its extremity.

The student will readily perceive how the above properties give a method for constructing a diameter to a set of chords, and in particular how to construct the axis of a given parabola. Thus the problem of Art. 137, to construct a tangent and normal to a given parabola at a given point, can now be solved even when the axis is not given.

If any point on a diameter is taken as a pole, its polar will be one of the system of hisected chords, of slope $m$.

For the pmle is $J^{\prime \prime}=\left(x^{\prime}, \frac{2 p}{m}\right)$, hernce the equation of its pmatar (Art. 127) is

$$
\begin{gathered}
\frac{2 p}{2 m} y=2 p\left(x+x^{\prime}\right) \\
y=m x+m x^{\prime}
\end{gathered}
$$

which is the equation of a chord of slope $m$. In other works. the tangents at the extremitien of a chord of the parabola inter. sect upoun the correspondiny diameter.
141. The equation of a parabola referred to any diameter and the tangent at its extremity as axes. In the simplest form of the equation of the parabola, vic.,

$$
\begin{equation*}
y^{2}=4 p x_{0} \tag{1}
\end{equation*}
$$

the coordinate axns are the principal diameter and the tangent at its extremity. Thess are the only pair of such lines that are perpendicular to each other (Art. 140). It is now desired to find the equation of the parabola, when referred to any diameter of the curve and the tangont at its extremity as axes.

Lat any diameter $O X X^{\prime}$ of the parabola (1) be the new $x$-axis, and the tangent $O Y^{n}$ at $O^{\prime}$ be the new $y$-axis, meoting the old $x$-axis at at angle $\theta$.

$$
\begin{equation*}
\text { If } \quad m=\tan \theta \tag{}
\end{equation*}
$$

then (Art. 185) the coördinates of $\sigma$ are $\frac{p}{m^{i}}$ and $\frac{2 p}{m}$ and the equation for transforming the equation from the old axes to a parallel set through the jwint $O^{\prime}$ are (Art 71),

Fio. 104.

$$
\begin{equation*}
x=x+\frac{p}{m} y=y+\frac{2 p}{m} \tag{3}
\end{equation*}
$$

Sulatituting these values in equation (1) gives

$$
\begin{equation*}
y^{2}+\frac{4 p}{m} y=4 p r \tag{4}
\end{equation*}
$$

To turn the $y$-axis to the final position, making an angle $\theta$ with the $x$-axis, the equations for transformation are ( $1 \mathrm{rl} .78,[25]$ ),
or, by equation (2),

$$
x^{\prime}=x^{\prime \prime}+y^{\prime \prime} \cos \theta, y^{\prime}=y^{\prime \prime} \sin \theta,
$$

$$
\begin{equation*}
x^{\prime}=x^{\prime \prime}+\frac{y^{\prime \prime}}{\sqrt{1+m^{2}}}, \text { and } y^{\prime}=\frac{m y^{\prime \prime}}{\sqrt{1+m^{2}}} . . . \tag{5}
\end{equation*}
$$

Substituting these values in equation (4), it becomes

$$
\frac{m^{2}}{1+m^{2}} y^{y^{\prime 2}}=4 p x^{\prime \prime} ;
$$

or, dropping now the accents,

$$
\begin{equation*}
y^{2}=4 p\left(\frac{1+m^{2}}{m^{2}}\right) x, \tag{8}
\end{equation*}
$$

which is the required equation of the parabola.
This equation may, however, be written more simply. Observing (Art. 103) that $p\left(\frac{1+m^{2}}{m^{2}}\right)$ is the focal distance of the new origin $\alpha$, and representing that distance by $p^{\prime}$, equation ( (8) becomes

$$
\begin{equation*}
y^{2}=4 p^{\prime} x \tag{58}
\end{equation*}
$$

This equation is of the same form as equation (1), but is referred to oblique axes. In general, therefore, the equation

$$
y^{2}=k x
$$

represents a parabola, and $\frac{k}{4}$ is the distance of its focus from the origin.
Equation [58] states the following property for every point $P$ of the parabola:

$$
\overline{M^{\prime} P^{2}}=4 F O^{\prime} \cdot O^{\prime} M^{\prime} ;
$$

a property entirely analogous to that of Art. 106.

## EXERCISES

1. Find the diameter of $y^{2}=-7 x$, which bisects the chords parallel to the line $x-y+2=0$.
2. A diameter of the parabola $y^{2}=8 x$ passes through the point $(2,-3)$; what is the equation of its corresponding chords?
3. Find the equation of the diameter of the parabola $y^{2}=4 x+4$ which bisects the chords $2 y-3 x=k$.
4. Find the equation of the tangent to the parabola $(y-6)^{2}=8(x+2)$, which is perpendicular to the diameter $y-4=0$.

5 Show that the pule of any chord in on the diametars which eurme mponde to the chord.
6. What is chae equations of the parabola $y^{2}=8 x^{2}$, when owforred uo its diameter $y=5=0$ and the correnpmading tangent an cotiminate axes?
7. What is the equation of the parabola $(-+3)^{2}=12(y-1)$. when referreat to a diameter throught the groint $(3,4)$ and the corres spording tangent an cobollinater axen?
8. Find the pole of the diameter $y=t$ with refercnoe to the paralola $y^{3}=4 \mu x$.
9. The poblar of any point on a diameter is parallel to the correspumsing tangent of that diameter.

## EXAMPLES ON CHAPTER IX

Find the equation of a parabola with axis prarallel to the $x$-axis:

1. puassing through the points $(0,0),(3,2),(3,-2)$;
2. puasing through the points $(3,1),(-3,4),(-1,2)$;
3. through the pwint $(4,-5)$, with the vertex at the point ( $3,-\bar{j}$ ).
4. A parabola whose axis is parallell to the $y$-axim passess chrough the points $(-1,2),(\%, 10)$, and $(-3,5)$; find its equation.
5. Find the vertex and axis of the parabola of Ex. \&

Find the equation of a parabola
6. if the axis and dinectrix are taken as coordinate axes
7. with the focus at the origin, and the $y$-axis parallel to the directrix.
a. tangent to the line $4 y=3 x-12$, the equation being in the simplest standard form.
9. If the axis of the parabola coincides with the $x$-axim, and a fueal radius of lengets 10 coincides with the line $4 x-3 y=8$.
10. Two equal paraloplas have the satne vertex, and their axes ane pern pendicular; find their common chond and eommon tangent (ef. Fis. 10. 1.224).
11. At what angle do the parabolas of Ex. 10 intersect
12. Two tangents to a juarabola are perpendicular to each other; fimed the product of the corresponding sub-tasigents

Find the locus of the middle proint
23. of all the ordinatess of a puerabola.
14. of all chords passing thruugh the vertex
15. From any point on the latus rectum of a parabola, perpendiculars are drawn to the tangents at its extremities; show that the line joining the feet of these perpendiculars is a tangent to the parabola.
16. If tangents are drawn to the parabola $y^{2}=4 \mathrm{ax}$ from any point on the line $x+4 a=0$, their chord of contact will subtend a right angle at the vertex.

Two tangents of slope $m$ and $m$ ', respectively, are drawu to a parabola; find the locus of their intersection:
17. if $m m^{\prime}=k$;
18. if $\frac{1}{m}+\frac{1}{m^{\prime}}=k$;
19. if $\frac{1}{m}-\frac{1}{m^{\prime}}=\mathbb{k}$.
20. Find the locus of the center of a circle which passes through a given point, and touches a given liue.
21. The latus rectum of the parabola is a third proportional to any abscissa and the corresponding ordinate.
22. Find the locus of the point of intersection of tangents drawn at points whose ordinates are in a constant ratio.
23. What is the equation of the chord of the parabola $y^{2}=3 x$ whose middle point is at $(2,1)$ ?
24. A double ordinate of the parabola $y^{2}=4 p x$ is $8 p$; prove that the lines from the vertex to its two ends are perpendicular to each other.
25. Find the locus of the center of a circle which is tangent to a given circle and also to a given straight line.
26. Find the intersections of a normal to the parabola with the curve, and the length of the intercepted portion.
27. Prove that the locus of the middle point of the normal intercepted between the parabola and its axis is a parabola whose vertex is the focus, and whose latus rectum is one fourth that of the original parabola.
28. Prove that two confocal parabolas, with their axes in opposite directions, intersect at right angles.
29. Find the equation of the parabola when referred to tangents at the extremities of the latus rectum as coordinate axes.
30. The product of the tangent and normal lengths for a certain point of the parabola $y^{2}=4 p x$ is twice the square of the corresponding ordtnate, find the point and the slope of the tangent line.

## CHAPTER X

$$
\text { THE ELLIPSE, } \frac{x^{2}}{a^{2}}+\frac{y^{2}}{b^{2}}=1
$$

142. Review. In Chapter VIII the nature of the ellipse has been briefly discussed, and its equation found in the two standard forms :

$$
\frac{x^{2}}{a^{2}}+\frac{y^{2}}{b^{2}}=1
$$

when the axes of the curve are coincident with the coordinate axes; and

$$
\frac{(x-h)^{2}}{a^{2}}+\frac{(y-k)^{2}}{b^{2}}=1
$$

when the axes of the curve are parallel to the coordinate axes, and the center is the point ( $h, k$ ). In the present chapter it is desired to study some of the intrinsic properties of the ellipse, i.e., properties which belong to the curve but are independent of the coördinate axes ; and these can for the most part be obtained most easily from the simpler equation,

$$
\frac{x^{2}}{a^{2}}+\frac{y^{2}}{b^{2}}=1
$$

The ellipse $\frac{x^{2}}{a^{2}}+\frac{y^{2}}{y^{2}}=1$ has its eccentricity given by the relation $b^{2}=a^{2}\left(1-c^{2}\right)$, i.e., $c^{2}=\frac{a^{2}-b^{2}}{a^{2}}$; its foci are the two points $( \pm a e, 0)$, and its directrices the lines $x= \pm{ }_{e}^{a}$ (Art. 110). If the axes are equal, so that $b=a$, the curve takes the special form of the circle, with eccentricity $e=0$,
the two foci coincident at the center, and the directrices infinitely distant.

The equation $\frac{x_{1} x}{a^{2}}+\frac{y_{1} y}{b^{2}}=1$ represents the polar of the point ( $x_{1}, y_{1}$ ) with respect to the ellipse; if the point is outside the curve, this polar line is its chord of contact; if upon the curve, the polar is the tangent at that point (Arts. 122, 126, 127).

These facts will be assumed in the following work.
143. The equation of the tangent to the ellipse $\frac{x^{2}}{a^{2}}+\frac{y^{2}}{b^{2}}=1$ in terms of its slope. The equation of a line having the given slope $m$ is

$$
\begin{equation*}
y=m x+k \tag{1}
\end{equation*}
$$

it is desired to find that value of $k$ for which this line will become tangent to the ellipse whose equation is

$$
\begin{equation*}
\frac{x^{2}}{a^{2}}+\frac{y^{2}}{b^{2}}=1 \tag{2}
\end{equation*}
$$

Considering equations (1) and (2) as simultaneous, and eliminating $y$, the resulting equation

$$
\begin{equation*}
\left(b^{2}+a^{2} m^{2}\right) x^{2}+2 a^{2} m k x+a^{2} k^{2}-a^{2} b^{2}=0 \tag{3}
\end{equation*}
$$

determines the abscissas of the two points of intersection of the curves (1) and (2). When the curves are tangent, these abscissas are equal; therefore
i.e.,

$$
a^{4} m^{2} k^{2}-\left(b^{2}+a^{2} m^{2}\right)\left(a^{2} k^{2}-a^{2} b^{2}\right)=0
$$

and

$$
k^{2}=a^{2} m^{2}+b^{2}
$$

Hence

$$
k= \pm \sqrt{a^{2} m^{2}+b^{2}}
$$

$$
\begin{equation*}
y=m x \pm \sqrt{a^{2} m^{2}+b^{2}} \tag{59}
\end{equation*}
$$

is the equation of a tangent to the ellipse $\frac{x^{2}}{a^{2}}+\frac{y^{2}}{b^{2}}=1$, for all values of $m$.

Equation [59] shows that there are tho tangents to an ellipso parallel to any given line; and also (Art. 125), that there are two tangents to an ellipse from any external pwint.
144. The sum of the focal distances of any point on an ellipse is constant ; it is equal to the major axis.

The ellipse $\frac{x^{3}}{a^{2}}+\frac{y^{2}}{b^{2}}=1$ has its foci at the points

$$
F_{1} \equiv(-a e, 0) \text { and } F_{s} \equiv(a e, 0) ;
$$

with $b^{3}=a^{2}-a^{2} e^{3}$. (Cf. Art. 110.)
Let $P_{1} \equiv\left(x_{1}, y_{1}\right)$ be any point on the curve, so that

$$
y_{1}^{2}=b^{2}-\frac{b^{2} x_{1}^{2}}{a^{2}}
$$

Then, $\quad F_{1} P_{1}^{2}=\left(x_{1}+a e\right)^{2}+y_{1}^{2}=a^{2} e^{2}+2 a e x_{1}+x_{1}^{2}+y_{1}^{2}$

$$
=a^{2} e^{2}+2 a e x_{1}+x_{1}^{2}+b^{2}-\frac{b^{2} x_{1}^{2}}{a^{2}}
$$

$$
=a^{2} e^{2}+2 a c x_{1}+\frac{\left(a^{2}-b^{3}\right)}{a^{3}} x_{1}{ }^{2}+a^{2}-a^{3} c^{2}
$$

$$
=a^{2}+2 a e x_{1}+e^{2} x_{1}^{2} ;
$$

i.e.,

$$
F_{1} P_{1}=a+e x_{1} .
$$

Again, $\quad F_{2} P_{1}^{2}=\left(x_{1}-u e\right)^{2}+y_{1}{ }^{2}=a^{2} e^{2}-2 a e x_{1}+x_{1}{ }^{2}+y_{1}{ }^{2}$

$$
=a^{2}-2 a e x_{1}+e^{2} x_{1}^{2}
$$

$$
F_{2} P_{1}=a-e x_{1}
$$

Hence, by addition,

$$
F_{1} P_{1}+F_{2} P_{1}=2 a ;
$$

i.e., the sum of the focal distances of any point on an ellipse is constant; it is equal to the major axis.

This property gives an easy method of finding the foci of an ellipse when the axes $A^{\prime} A$ and $B^{\prime} B$ are given.

For

$$
F_{1} B+F_{2} B=2 a
$$

but

$$
F_{1} O=O F_{2},
$$

$\therefore \quad F_{2} B=F_{1} B=a$.
Hence, to find the foci, describe ares with $B$ as center and $a=O A$ as radius, cutting $A^{\prime} A$ in the points $F_{1}$ and $F_{2}$; these points are the required foci.
145. Construction of the ellipse. The property of Art. 144 is sometimes given as the definition of the ellipse ; viz. the ellipse is the locus of a point the sum of whose distances from two fixed points is constant. This definition leads at once to the equation of the curve (cf. Ex. 5, 1. 67); and also gives a ready method for its construction.
(a) Comstruction by separate points. Let $A^{\prime} A$ be the given sum of the focal distances, i.e., the major axis of the ellipse; and $F_{1}$ and $F_{2}$ be the given fixed points, the foci. With either focus as center, and with any radius $A^{\prime} R<A^{\prime} A$ describe an are; then with the other focus as center, and radius $R A$, describe an are cutting the first arc in two points. These are points of the ellipse. In the same way
as many points as desired may be constructed; a smooth curve connecting these points is approximately an cllipme.

( $\beta$ ) Construction by a continuously moving point. Fix two upright pins at the foci, and over them place a loop of string, equal in length to the major axis plus the distance between the foci. Press a pencil point against the cord so as to keep it taut. As the pencil moves around the foci, it will trace an ellipse.

## EXERCISES

1. Construct an ellipse with semi-axes 8 em and $0^{0-}$.
2. Construct an ellipse with semi-ares $5^{\mathrm{mm}}$ and 12 m .
3. Construct an ellipme with the distance between the foci 24 , and the minor axis of length 10 .
4. Write the equation of the polar of the left-hand focus of the ellipse $\frac{x^{3}}{9}+\frac{y^{2}}{4}=1$. What line is this?
5. By employing equation [58], find the tangent to the ellipee $16 x^{8}+23 y^{2}=400$, and passing through the point ( 3,4 ).
6. By the method of Ex. 17, p. 225, show that an ellipse is concave toward its center.
7. Through what point of the ellipee $\frac{x^{3}}{a^{2}}+\frac{y^{3}}{b^{2}}=1$ must a tangent and normal be drawn, to form with the maxis an isosceles triangle?
8. Write the equations of the tangent and normal at the pasitive end If the latus rectum of the ellipes $x^{2}+4 y^{2}=4$. Where do these lines cut the $x$-axis?
9. Tangents to the ellipse $4 x^{2}+3 y^{2}=5$ are inclined at $60^{\circ}$ to the $x$-axis; find the points of contact.
10. Find the equation of an ellipse (center at the origin) of eccentricity $\frac{1}{3}$, such that the subtangent for the point $\left(3, y^{2}\right)$ is $\left(-y_{j}\right)$.
11. Find the chord of contact for tangents from the point $(3,2)$ to the ellipse $x^{2}+4 y^{2}=4$. Find also the equation of the line from $(3,2)$ to the middle point of this chord.
12. Find the tangents to the ellipse $7 x^{2}+8 y^{2}=56$ which make the angle $\tan ^{-1} 3$ with the line $x+y+1=0$.
13. Find the product of the two segments into which a focal chord is divided by the focus of an ellipse, - using Art. 131.
14. Find the equation of a tangent, and also of a normal, to the ellipse $x^{2}+4 y^{2}=16$, each parallel to the line $3 x-4 y=5$.
15. Find the pole of the line $3 x-4 y=5$ with reference to the ellipwe $x^{2}+4 y^{2}=16$; also the intercepts on the axes made by a line through the pole and perpendicular to the polar.
16. Find the points on the ellipse $b^{2} x^{2}+a^{2} y^{2}=a^{2} l^{2}$, such that the tangent makes equal (numerical) angles with the axes; such that the subtangent equals the subnormal.
17. Auxiliary circles. Eccentric angle. The circumscribed and inscribed circles for the ellipse (Fig. 107) are called auxiliary circles, and bear an important part in the theory of the ellipse. Let the equation of the ellipse be

$$
\begin{equation*}
\frac{x^{2}}{a^{2}}+\frac{y^{2}}{b^{2}}=1 \tag{1}
\end{equation*}
$$

The circle described on its major axis as diameter is called the major auxiliary circle; its equation is

$$
\begin{equation*}
x^{2}+y^{2}=a^{2} \tag{2}
\end{equation*}
$$

and the circle on the minor axis as diameter is the minor auxiliary circle; its equation is

$$
\begin{equation*}
x^{2}+y^{2}=b^{2} \tag{8}
\end{equation*}
$$

If $\angle A O Q$ is any angle $\phi$ at the center of the cllipmes, with the initial side on the major axis, and the terminal side cutting the auxiliary circles in $\boldsymbol{R}$ and $Q$, respectively; and if

Fio. 100.
$P$ is the intersection of the abscisss $L R$ with the orlinate $M Q$, then $P$ is a point on the ellipse.

For the coirdinates of $P$ are

$$
O M=O Q \cos \phi \text { and } M P=M^{\prime} R=O R \sin \phi .
$$

i.e.,

$$
x=a \cos \phi, \quad y=b \sin \phi .
$$

Now these values satisfy the equation of the ellipse; for, substituting them in equation (1), gives

$$
\frac{a^{2} \cos ^{2} \phi}{a^{2}}+\frac{b^{2} \sin ^{2} \phi}{b^{2}}=\cos ^{2} \phi+\sin ^{2} \phi=1 ;
$$

hence $\boldsymbol{P}$ is a point of the ellipse.
The points $P, Q$, and $R$ are called corresponding points. The angle $\phi$ is the eccentric angle of the point $P ;{ }^{\circ}$ and the

[^37]two equations [60] are equations of the ellipse in terms of the eccentric angle, for together they express the condition that the point $P$ is on the ellipse (1).*

Since, in the figure, $\triangle O M^{\prime} R$ and $O M Q$ are similar, it follows that

$$
M P: M Q=O R: O Q=b: a
$$

and

$$
O M^{\prime}: O M=O R: O Q=b: a ;
$$

that is, the ordinate of any point on the ellipse is to the ordinate of the corresponding point on the major auxiliary circle in the ratio ( $b: a$ ) of the semi-axes. Similarly for the abscissas of the corresponding points $R$ and $P$.
147. The subtangent and subnormal. Construction of tangent and normal.

Let

$$
\begin{equation*}
\frac{x^{2}}{a^{2}}+\frac{y^{2}}{b^{2}}=1 \tag{1}
\end{equation*}
$$

be a given ellipse, then

$$
\begin{equation*}
\frac{x_{1} x}{a^{2}}+\frac{y_{1} y}{b^{2}}=1 \tag{2}
\end{equation*}
$$

is the tangent to it at a point $P_{1} \equiv\left(x_{1}, y_{1}\right)$. Let this tangent cut the $x$-axis at the point $T$. Draw the ordinate $M P_{1}$.

Then the subtangent is, by definition, $T M$; and its numerical value is

$$
M T=O T-O M
$$

but, from equation (2), $O T=\frac{a^{2}}{x_{1}}$; and $O M=x_{1}$;
hence
i.e.,

$$
\begin{aligned}
& M T=\frac{a^{2}}{x_{1}}-x_{1} \\
& T M=\frac{x_{1}^{2}-a^{2}}{x_{1}}
\end{aligned}
$$

[^38]Hence the value of the subtangent, corresponding to asy point of the ellipse whose equation is (1), depends only upon the major axis, and the abscissas of the point; therefore, if a series of ellipses have the same major axis, tangenta drawn to them at the points having a common abscissa will cut the major aris (extended) in a common point.

This fact suggests a method for constructing a tangent and normal to an ellipse, at a given point: draw the major anxiliary circle; at $Q$ on this circle, and in $M P_{1}$ extended, draw a tangent to the circle. This will cut the axis in $T$ : and $P_{1} T$ will be the required tangent to the ellipse at $P_{1}$. The normal $P_{1} N$ may then be drawn perpendicular to $P_{1} T$.

The equation of the normal through $P_{1}$ is (cf. eq. [51])

$$
y-y_{1}=\frac{a^{2} y_{1}}{l_{1}^{2} r_{1}}\left(x-x_{1}\right) ;
$$

therefore the $x$-intercept of the normal at that point is

$$
O N=\frac{a^{2}-b^{2}}{a^{3}} x_{1}=e^{2} x_{1}
$$

But the subnormal corresponding to $P_{1}$ is

$$
M N=O N-O M
$$

and

$$
O M=x_{1}
$$

therefore

$$
\begin{aligned}
M N & =\frac{a^{2}-b^{2}}{a^{2}} x_{1}-x_{1} \\
& =-\frac{b^{2}}{a^{2}} x_{1}=\left(e^{2}-1\right) x_{1}
\end{aligned}
$$

Note. From the value of $O N$ it follows that the normal to an ellipse does not, in general, pass through the center, but passes between the center and the foot of the ordinate; the extremities of the axes of the curve being exceptional points. If, however, $a=b$, then $e=0$, the curve is a circle, and every normal passes through the center (cf. Art. 85).
148. The tangent and normal bisect externally and internally, respectively, the angles between the focal radii of the point of contact.

Let the equation of the given ellipse be $\frac{x^{2}}{a^{2}}+\frac{y^{2}}{b^{2}}=1$; also let $F_{1}$ and $F_{2}$ be the foci, and $P_{1} \equiv\left(x_{1}, y_{1}\right)$ any given point on the curve. Draw the tangent $T P_{1}$, the normal $P_{1} N$, and also the lines $F_{2} P_{1}$ and $F_{1} P_{1} W$.

Then

$$
\begin{align*}
F_{1} V & =F_{1} O+O V=a e+e^{2} x_{1}  \tag{Art.14T}\\
& =e\left(a+e x_{1}\right) \\
N F_{3} & =O F_{3}-O N=a e-e^{2} x_{1} \\
& =e\left(a-e x_{1}\right) ;
\end{align*}
$$

[Art, 144]
also

$$
F_{1} P_{1}=a+e x_{1}
$$

and

$$
F_{2} P_{1}=a-e x_{1} .
$$

Hence

$$
F_{1} N: N F_{3}=F_{1} P_{1}: P_{1} F_{2}
$$

and, by a theorem of plane geometry, this proportion proves that the normal $P_{1} N$ bisects the angle $F_{1} P_{1} F_{3}$ between the focal radii. Again, since the tangent is perpendicular th the normal, the tangent $P_{1} T$ will bisect the external angle $F_{2} P_{1} W$.

This proposition leads to a second method of constructing the tangent and normal to an ellipse at a given point (ef. Art. 147). First determine the foei, $F_{1}$ and $F_{2}$ (Art. 144), then draw the focal radii to the given point and bisect the angle thus formed, - internally for the normal, externally for the tangent.
149. The intersection of the tangents at the extremity of a focal chord.

If $f^{\prime \prime} \equiv\left(x^{\prime}, y^{\prime}\right)$ be the intersection of two tangents to the ellipme

$$
\frac{x^{2}}{a^{2}}+\frac{y^{3}}{b^{3}}=1 \text {, }
$$

the equation of their chord of contact is (Art. 126)

$$
\begin{equation*}
\frac{x^{2} x}{a^{3}}+\frac{y^{\prime} y}{b^{2}}=1 . \tag{1}
\end{equation*}
$$

If this chord passes through the focus $F_{2} \equiv(a e, 0)$, its equation must Ine satisfied by the coordinates of $F_{3}$; therefore

$$
\frac{x^{x} u e}{a^{3}}=1 \text {, i.e., } x=\frac{a}{e}
$$

and the point of intersection $P^{\prime}$ is on the line, $x=\frac{a}{e} ;$ i.e., on the directrix corresponding to the focus $F_{y}$. Similarly, if the chord passes through the focus $F_{1} \equiv(-a e, 0)$, the point $P^{\prime}$ is on the directrix $x=-\frac{a}{e}$.

Hence, the tungents at the extremities of a focal chord intersect upon the corresponding directrix.

Again, the line joining the intersection $P^{\prime} \equiv\left(\frac{a}{e}, y^{\prime}\right)$ to the focus has the slope

$$
m^{\prime}=\frac{y_{2}-y_{1}}{x_{2}-x_{1}}=\frac{y^{\prime}}{\frac{1}{e}-a e}=\frac{e y^{\prime}}{a\left(1-e^{2}\right)}=\frac{a e y^{\prime}}{b^{2}} ;
$$

while the slope of the focal chord (1) is
hence

$$
\begin{gathered}
m=-\frac{b^{2} x^{\prime}}{a^{2} y^{\prime}}=-\frac{b^{2}}{a e y^{\prime}} ; \\
m^{\prime}=-\frac{1}{m^{\prime}}
\end{gathered}
$$

and therefore the line joining the focus to the intersection of the tangents at the ends of a focal chord is perpendicular to that chord.
150. The locus of the foot of the perpendicular from a focus upon a tangent to an ellipse. Let the equation of a tangent to the ellipse (Art. 143), whose equation is

$$
\begin{equation*}
\frac{x^{2}}{a^{2}}+\frac{y^{2}}{b^{2}}=1, \tag{1}
\end{equation*}
$$

be written in the form $y=m x+\sqrt{a^{2} m^{2}+b^{2}}$.
Then the equation of a perpendicular to (2), through the focus ( $a e, 0$ ), is

$$
\begin{equation*}
y=-\frac{1}{m}(x-a e), \quad \text { i.e., } x+m y=a e . \quad . \quad . \tag{3}
\end{equation*}
$$

If $P^{\prime} \equiv\left(x^{\prime}, y^{\prime}\right)$ is the point of intersection of (2) and (3), it is required to find the locus of $P$; i.e., to find an equation which will be satisfied by the coördinates $x^{\prime}, y^{\prime}$, whatever the value of $m$; this must be an equation involving $x^{\prime}$ and $y$, but free from $m$. Since $P^{\prime}$ is on both lines (2) and (3),
therefore

$$
\begin{equation*}
y^{\prime}-m x^{\prime}=\sqrt{a^{2} m^{2}+b^{2}}, \tag{4}
\end{equation*}
$$

and

$$
\begin{equation*}
x^{\prime}+m y^{\prime}=a e . \tag{5}
\end{equation*}
$$

The elimination of mis arcomplintiod most easily by spuarmg each member of equations (4) and (5), and adding :
this given $\quad\left(1+m^{5}\right) x^{4}+\left(1+m^{2}\right) y^{3}=a^{2} m^{3}+a^{2} \varepsilon^{3}+b^{4}$,
B.e.s

$$
\begin{aligned}
\left(1+m^{2}\right)\left(x^{2}+y^{2}\right) & =a^{2}\left(m^{8}+1\right) \\
x^{2}+y^{2} & =a^{3} .
\end{aligned}
$$

whence,
Hence, the print $I^{v}$ is on the circle

$$
x^{2}+y^{2}=a^{2} ;
$$

that is, the locus of the foot of a prerpendicular from either forme upon a tangent to the allipse is the major ausiliury circle.

## 151. The locus of the intersection of two perpendicular tangents to the ellipse.

Let the equation of any tangent to the ellipse $\frac{x^{2}}{a^{2}}+\frac{y^{2}}{b^{3}}=1$ he written in the form (Art. 148)

$$
\begin{equation*}
y-m x=\sqrt{a^{2} m^{3}+b^{2}}, \tag{1}
\end{equation*}
$$

then the equation of a perpendicular tangent is

$$
y+\frac{1}{m} x=\sqrt{\frac{a^{8}}{m^{2}}+b^{3}}
$$

$$
\begin{equation*}
m y+x=\sqrt{a^{2}+b^{2} m^{2}} . \tag{2}
\end{equation*}
$$

letting $P^{\prime} \equiv\left(x^{\prime}, y^{\prime}\right)$ be the proint of internection of these two tangentes, (1) and (2), it is required to find the lecus of $P$ as $m$ varies in value: that is, to find an equation hetween r $^{\prime}$ and $y^{\prime}$ which doess not involve m .

Proeeeding as in Art. 150; since $P^{v}$ is on both lines (1) and (2).
therefore
and $\quad m y^{\prime}+x^{\prime}=\sqrt{a^{3}+b^{3} m^{2}}$.
To eliminate $m$, square both equations, and add: this gives
i.e.

$$
\begin{aligned}
& y^{\prime}-m x^{\prime}=\sqrt{a^{2} m^{2}+b^{2}} \\
& m y^{\prime}+x^{\prime}=\sqrt{a^{3}+b^{2} m^{2}} .
\end{aligned}
$$

$$
\left(m^{2}+1\right) x^{2}+\left(m^{2}+1\right) x^{2} m\left(m^{2}+1\right) a^{2}+\left(m^{2}+1\right) k^{2}
$$

Therefore, the point of intersection of perpendicular tangenta is on the circle

$$
\begin{equation*}
x^{2}+y^{2}=a^{2}+b^{2} . \tag{81}
\end{equation*}
$$

which is called the director circle for the ellipme. The locus of the isuter section of tue perpendicular tumgenta to an ellipme is, then, tse director comie.

## EXERCISES

1. Prove that the two tangents drawn to an ellipse from any external point subtend equal angles at the focus.
2. Each of the two tangents drawn to the ellipse from a point on the directrix subtends a right angle at the focus.
3. A focal chord is perpendicular to the line joining its pole to the focus. Show that this is also true for a parabola.
4. The rectangle formed by the perpendiculars from the foci upon any tangent is constant ; it is equal to the square of the semi-minor-axis.
5. The circle on any focal distance as diameter touches the major auxiliary circle.
6. The perpendicular from the focus upon any tangent, and the line joining the center to the point of contact, meet upon the directrix.
7. The perpendicular from either focus, upon the tangent at any point of the major auxiliary circle, equals the distance of the corresponding point of the ellipse from that focus.
8. The latus rectum is a third proportional to the major and minor axes.
9. The area of the ellipse is mab.

Suggestion. Employ the fact, proved in Art. 14B, that the ordinate of an ellipse is to the corresponding ordinate of the major auxiliary circle as $b: a$, and thus compare the area of the ellipse with that of its major auxiliary circle.
152. Diameters. As already shown in Articles 129 and 139, the definition of a diameter as the locus of the middle points of a system of parallel chords leads directly to its equation.

Let $m$ be the slope of the given system of parallel chords of the ellipse whose equation is

$$
\begin{align*}
& \frac{x^{2}}{a^{2}}+\frac{y^{2}}{b^{2}}=1  \tag{1}\\
& y=m x+c \tag{2}
\end{align*}
$$

and let
he the equation of one of theme chords, which meets the curve in the two points $P_{1} \equiv\left(x_{1}, y_{1}\right)$ and $P_{2} \equiv\left(x_{2}, y_{2}\right)$. Let $P^{\prime} \equiv\left(x^{\prime}, y^{\prime}\right)$, be the middle point of this chord, so that

$$
\begin{equation*}
x^{\prime}=\frac{x_{1}+x_{2}}{2}, \quad y^{\prime}=\frac{y_{1}+y_{3}}{2} \tag{8}
\end{equation*}
$$

Fso. 110
The coordinates of $P_{1}$ and $P_{2}$ are found by solving (1) and $(2)$ as simultaneous equations, therefore the abscissas $x_{1}$ and $x_{2}$ are the roots of the equation
*

$$
\begin{equation*}
\left(a^{2} m^{2}+b^{2}\right) x^{2}+2 a^{2} c m x+a^{2} c^{2}-a^{2} \ell^{2}=0 \tag{4}
\end{equation*}
$$

and the ordinates $y_{1}$ and $y_{2}$ are roots of the equation

$$
\begin{equation*}
\left(a^{2} m^{2}+l^{2}\right) y^{2}-2 l^{2} c y+l^{2} c^{2}-a^{2} b^{2} m^{2}=0 \ldots \tag{5}
\end{equation*}
$$

Hence, by Art. 11, the coürdinates of $J^{\prime \prime}$ are

$$
\begin{equation*}
x^{\prime}=-\frac{a^{2} c m}{a^{2} m^{2}+b^{2}} \quad y^{\prime}=\frac{b^{2} c}{a^{2} m^{2}+b^{2}} . \quad . \tag{6}
\end{equation*}
$$

Now, by varying the value of $c$, equation (6) gives the coordinates of the middle point for each of the chords of the given set. It is required to find the locus of $P^{\prime}$ for all values of $c$, i.e., to find an equation satisfied by $x^{\prime}$ and $y^{\prime}$.
and not dependent upon the value of $c$. If $x^{\prime}$ be divided by $y^{\prime}$, the $c$ is eliminated from the equations (6), giving

$$
\begin{equation*}
\frac{x^{\prime}}{y^{\prime}}=-\frac{a^{2}}{b^{2}} m \tag{7}
\end{equation*}
$$

Therefore the coördinates of the middle point of every chord of slope $m$ satisfy the equation

$$
\frac{x}{y}=-\frac{a^{2}}{b^{2}} m
$$

or,

$$
\begin{equation*}
y=-\frac{b^{2}}{a^{2} m} x \tag{62}
\end{equation*}
$$

which is therefore the equation of the diameter bisecting the chords of slope $m$.

The form of equation [62] shows that every diameter of the ellipse passes through the center.
153. Conjugate diameters. Since every diameter passes through the center of the ellipse, and since, by varying the slope $m$ of the given set of parallel chords, the corresponding diameter may be made to have any required slope, therefore it follows that every chord which passes through the center of an ellipse is a diameter, corresponding to some set of parallel chords. In particular, that one of the set of chords given by equation (2), Art. 152, which passes through the center, -i.e., the chord whose equation is

$$
\begin{equation*}
y=m x \tag{63}
\end{equation*}
$$

is a diameter. This diameter bisects the chords parallel to the line [62]; for if $m^{\prime}$ be the slope of the line [62],
then

$$
m^{\prime}=-\frac{b^{2}}{a^{2} m}
$$

hence,

$$
\begin{equation*}
m m^{\prime}=-\frac{b^{2}}{a^{2}} \tag{64}
\end{equation*}
$$

and this equation expresses the condition that line [6\%], which has the slope $\mathrm{m}^{\prime}$, shall biseet the chords of slope $m$ (Art. 152). But conversely, it expresses almo the condition that the line [63] which has the slope $m$ shall bisect the chords of slope $\mathrm{m}^{\prime}$. Hence each of the lines [62] and [68] hisects the chords parallel to the other. Hence, if one diameter bisects the chords parallel to a second, then also the second diameter bisects the chords parallel to the first. Such diameters are called conjugate to each other.

Each line of the set of parallel chords in general cuts the ellipse in two distinct points, and the further the chord is from the center, the nearer these two points are to each other, and to their mid-point. In the limiting position, the chord becomes a tangent, with the two intersection points and their mid-point coincident at the point of tangency. Therefore, the tangent at the end of a diameter is parallel to the conjugate diameter. This property, with that of $\mathbf{A r t} .152$, suggests a method for construeting conjugate diameters: first draw a tangent at an extremity of a given diameter (Art. 147), then a line drawn parallel to this tangent through the center of the ellipse is the required conjugate diameter. (See Fig. 111.)
154. Given an extremity of a diameter, to find the extremity of its conjugate diameter.

Let $P_{1} w\left(x_{1}, y_{1}\right)$ be an extromity of a given diameter (Fig. 111), then $P_{3}=\left(-x_{1},-y_{1}\right)$ will be the other extremity. Let $P_{1}^{\prime} \equiv\left(x_{1}^{\prime}, y_{1}^{\prime}\right)$ and $r_{i}^{\prime}=\left(-x_{1}^{\prime},-y_{i}^{\prime}\right)$ be the extremities of the conjugate diameter. thet the equation of the ellipse be

$$
\begin{equation*}
\frac{x^{2}}{a^{2}}+\frac{y^{2}}{b^{2}}=1 \text {; } \tag{1}
\end{equation*}
$$

then the equation of the given diameter $P_{1} P_{2}$ is

$$
\begin{equation*}
y=\frac{y_{1}}{x_{1}} x_{1} \tag{2}
\end{equation*}
$$

and that of the conjugate diameter $P_{1}{ }^{\prime} P_{2}^{\prime}$, through the center and parallel to the tangent at $P_{1}$ is

$$
\begin{equation*}
\frac{x_{1} x}{a^{2}}+\frac{y_{1} y}{b^{2}}=0 . \tag{8}
\end{equation*}
$$

The coördinates of $P_{1}^{\prime}$ and $P_{2}^{\prime}$, in terms of $x_{1}, y_{1}, a$, and $b$, are given by equations (1) and (3), considered as simultaneous; hence, eliminating $y$ between these equations, and remembering that the point $P_{1}$ is on the ellipse (1) and that therefore $b^{2} x_{1}^{2}+a^{2} y^{2}=a^{2} b^{2}$, the abscissas of the points $P_{1}^{\prime}$ and $P_{2}{ }^{\prime}$ are given by the equation

$$
x^{2}=\frac{a^{2} y^{2} L^{2}}{b^{2}} ;
$$

i.e.,

$$
x_{1}^{\prime}=-\frac{a}{b} y_{1} \text { and } x_{2}^{\prime}=\frac{a}{b} y_{1} .
$$

Substituting these values in equation (3), gives for the corresponding ordinates,

$$
y_{1}^{\prime}=\frac{b}{a} x_{1} \quad \text { and } \quad y_{2}^{\prime}=-\frac{b}{a} x_{1} .
$$

Therefore the required extremities of the conjugate diameter are

$$
P_{1}^{\prime} \equiv\left(-\frac{a}{b} y_{1}, \frac{b}{a} x_{1}\right) \text { and } P_{2}^{\prime} \equiv\left(\frac{a}{b} y_{1},-\frac{b}{a} x_{1}\right) \text {. }
$$

155. Properties of conjugate diameters of the ellipse. (a) It has been seen (Art. 153) that two diameters are conjugate when their slopes satisfy the relation

$$
\begin{equation*}
m m^{\prime}=-\frac{b^{2}}{a^{2}} \tag{1}
\end{equation*}
$$

It follows, since the product of their slopes is negative, that with the exception of the case where one diameter is the minor axis itself, conjugate diameters do not both lie in the ame quadrant formed by the axes of the curve.
(8) From the definition (Art. 153) it is evident that the minor and major axes of the elligse are a pair of conjugate diameters, and they are at right angles to each other. Perpendicular lines, however, in general, fulfill the condition

$$
\begin{equation*}
m m^{\prime}=-1 ; \tag{2}
\end{equation*}
$$

hence, in general, equation (2) is not consistent with equation (1) for other values of $m$ and $m^{\prime}$ than 0 and $\propto$, - the slopes for the axes of the curves. But for $b^{3}=a^{2}$, i.e., for the circle, it is clear that every pair of eonjugate diameters matisfy equation (2), and are therefore perpendicular to each other. Hence, the major and minor axes of the ellipse are the only pair of conjugate diameters that are perpendicular to each other.
( $\boldsymbol{\gamma}$ ) If, in Fig. 111, the lengths of the conjugate semi-axes be $a^{\prime}=C P_{1}, b^{\prime}=C P_{1}^{\prime}$, then, since

$$
P_{1} \equiv\left(x_{1}, y_{1}\right), P_{1}^{\prime} \equiv\left(-\frac{a}{b} y_{1}, \frac{b}{a} x_{1}\right),
$$

$$
b^{2} x_{1}^{2}+a^{3} y_{1}^{2}=a^{2} b^{2}, \quad a^{\prime 2}=x_{1}^{2}+y_{1}^{2}
$$

and

$$
b^{\prime 2}=\frac{a^{2} y_{1}^{2}}{b^{2}}+\frac{b^{2} x_{1}^{2}}{a^{2}}
$$

therefore

$$
\begin{align*}
a^{\prime 2}+b^{\prime 2} & =\frac{b^{2} x_{1}^{2}+a^{2} y_{1}^{2}}{b^{2}}+\frac{a^{2} y_{1}^{2}+b^{2} x_{1}^{2}}{a^{2}} \\
& =a^{2}+b^{2} \tag{8}
\end{align*}
$$

i.e., the sum of the squares of two conjugate semi-diameters is constant; it is equal to the sum of the squares of the turo semiaxes.
(8) Referring again to Fig. 111, where $C N$ is perpendicular to the tangent at $P_{1}$, the conjugate diameters $P_{1} P_{2}$ and $P_{1}^{\prime} P_{2}^{\prime}$ intersect at an angle $\psi$ such that

$$
\psi=\angle P_{1} C P_{1}^{\prime}=90^{\circ}+\angle P_{1} C N ;
$$

$\therefore \quad \sin \psi=\cos \angle P_{1} O N=\frac{C N}{C P_{1}}$.
But, by Art. 64, since the equation of the tangent at $P_{1}$ is

$$
b^{2} x_{1} x+a^{2} y_{1} y=a^{2} b^{2},
$$

$$
C N=\frac{a^{2} b^{2}}{\sqrt{b^{4} x_{1}^{2}+a^{4} y_{1}^{2}}}=\frac{a b}{\sqrt{\frac{a^{2} y_{1}{ }^{2}}{b^{2}}+\frac{b^{2} x_{1}^{2}}{a^{2}}}}=\frac{a b}{b^{\prime}} ;
$$

but

$$
\begin{gather*}
C P_{1}=a^{\prime}, \\
\sin \psi=\frac{a b}{a^{\prime} b^{\prime}}, \tag{4}
\end{gather*}
$$

hence
and the angle between two conjugate diameters is $\sin ^{-1} \frac{a b}{a^{\prime} b^{\prime}}$.
( $\epsilon$ ) Tangents at the extremities of a pair of conjugate diameters form a parallelogram circumscribed about the ellipse ; its sides are parallel to, and equal in length to, the conjugate diameters. Since the area of a parallelogram is equal to the product of its adjacent sides and the sine of the included angle, therefore the area of this circumscribed parallelogram is $4 a^{\prime} b^{\prime} \sin \psi$, which, by (4), equals $4 a b$.

That is, the area of the parallelogram constructed upon any two conjugate diameters is constant; it is equal to the area of the rectangle upon the axes.
(૬) A simple relation exists between the eccentric angles of the extremities of two conjugate diameters.

Let the eccentric angle of $P_{1} \equiv\left(x_{1}, y_{1}\right)$ be $\phi_{1}$ (Fig. 112), and of $P_{2} \equiv\left(x_{2}, y_{2}\right)$ be $\phi_{2}$; then the slopes of the corjugate diameters may be written (cf. Art. 146),
for $C P_{1}$

$$
\begin{aligned}
& m=\frac{y_{1}}{x_{1}}=\frac{b \sin \phi_{1}}{a \cos \phi_{1}} \\
& m^{\prime}=\frac{y_{3}}{x_{2}}=\frac{b \sin \phi_{2}}{a \cos \phi_{3}} \\
& m m^{\prime}=-\frac{b^{3}}{a^{3}}
\end{aligned}
$$

[Art. 155 (a)]

hence
giving
that is,
whence

$$
\frac{b^{2} \sin \phi_{1} \sin \phi_{3}}{a^{2} \cos \phi_{1} \cos \phi_{5}}=-\frac{b^{3}}{a^{3}},
$$

$$
\frac{\sin \phi_{1} \sin \phi_{2}}{\cos \phi_{1} \cos \phi_{2}}=-1 ;
$$

$\sin \phi_{2} \sin \phi_{1}+\cos \phi_{2} \cos \phi_{1}=0$,

Therefore

$$
\begin{gathered}
\cos \left(\phi_{2}-\phi_{1}\right)=0 . \\
\phi_{2}-\phi_{1}=90^{\circ}
\end{gathered}
$$

and the eccentric angles of the extremities of two conjugate diameters differ by a right angle.
156. Equi-conjugate diameters. If two conjugate diameters be equal to each other, e.g. if $C P_{1}=C P_{3}$ (see Fig. 112), then the properties given in the preceding article lead to other simple ones.

Let $\phi_{1}$ be the eccentric angle of $P_{1}$, then $\phi_{1}+90^{\circ}$ is the eccentrie angle for $P_{3}$; hence the coobrdinates of $P_{1}$ and $P_{3}$ are (a cos $\phi_{1} b$ sin $\phi_{1}$ ) and ( $-a \sin \phi_{v}, b \cos \phi_{1}$ ), and since

$$
a^{\prime}=v,
$$

therefore
i.e.,

Hence

$$
\begin{gathered}
a^{2} \cos ^{2} \phi_{1}+b^{2} \sin ^{2} \phi_{1}=a^{2} \sin ^{2} \phi_{1}+b^{2} \cos ^{2} \phi_{1} \\
\tan ^{2} \phi_{1}=1 \\
\phi_{1}=45^{\circ} \text { or } 135^{\circ}
\end{gathered}
$$

for the extremities of equi-conjugate diameters, and the extremities are

$$
P \equiv\left(x_{1}, \frac{b}{a} x_{1}\right), \quad P_{2} \equiv\left(-x_{1}, \frac{b}{a} x_{1}\right)
$$

The equations of these diameters are

$$
y=\frac{b}{a} x, \text { and } y=-\frac{b}{a} x
$$

Evidently these lines are the diagonals of the rectangle formed on the axes of the curve.

By Art. 155, $(\gamma)$, the length of each equi-conjugate semi-diameter is

$$
a^{\prime}=\sqrt{\frac{a^{2}+b^{2}}{2}}
$$

## EXERCISES

1. Find the diameter of the ellipse $\frac{x^{2}}{10}+\frac{y^{2}}{9}=1$ which bisects the chords parallel to the line $3 x+5 y+7=0$.
2. Find the diameter conjugate to that of exercise 1.
3. Show that the lines $2 x-y=0, x+3 y=0$ are conjugate diameters of the ellipse $2 x^{2}+3 y^{2}=4$.
4. For the ellipse $b^{2} x^{2}+a^{2} y^{2}=a^{2} b^{2}$, write the equations of diameters conjugate to the line

$$
\text { (a) } a x=b y, \quad(\beta) b x=a y
$$

5. Prove that the angle between two conjugate diametors is a maximum when they are equal.
6. Show that the pair of diameters drawn parallel to the chords joiring the extremities of the axes are equal and conjugate.
7. What are the equations of the pair of equi-conjugate diameters of the ellipse $16 y^{2}+9 x^{2}=144$ ?
8. Two conjugate diameters of the ellipse $\frac{x^{2}}{16}+\frac{y^{2}}{9}=1$ have the slopes $\frac{1}{\text { and }}-\frac{\text { ? }}{}$, respectively; find their lengths.
9. Given the ellipse $x^{2}+5 y^{3}=5$, find the eccentric angle for the point whose ahscissa is 1 . Also find the diameter conjugate to the one passing through this point.
10. Given the ellipme $8 x^{8}+1 y^{3}=12$, find the conjugate diameters tor the point whose ectentrie angle is $3 \mathrm{w}^{\circ}$.
11. Find the lengthe of the diameters in exereime 10.
12. The lengths of the chord joining the extremities of any two comjugater diametern of the ellipme $\frac{x^{2}}{a^{2}}+\frac{y^{3}}{b^{2}}=1$ is $\sqrt{a^{2}+b^{3}+a^{15} c^{3} b i l l}-\phi$. Find its greatent value. What is the corresponding value of $\phi$ ?
13. The area of a triangle inscritied in an ellipue, if $\phi_{1} \phi_{2} \phi_{3}$ be the occentrio angles of the vertices, is

$$
\frac{1}{1} u b\left[\sin \left(\phi_{1}-\phi_{2}\right)+\sin \left(\phi_{3}-\phi_{1}\right)+\sin \left(\phi_{1}-\phi_{2}\right)\right] .
$$

14. Given the point $(-3,-1)$ on the ellipse $x^{3}+3 y^{2}=12$; find the corresponding point on the major auxiliary circle, and also find the eceentric angle of the given point.
15. Find the polar of the focus of an ellipme with reference to each auxiliary circle.
16. Find the pole of the directrix of the ellipse with reference to each auxiliary circle.
17. Prove analytically that tangents at the ends of any chord intersect on the diameter which bisects that chord.
18. Supplemental chords. The chorls drawn from any point of an ellipse to the extremities of a diameter are called supplemental chorls. Such chords are always parallel to a pair of conjugate diameters, simes their slopes satisfy the relation

$$
m m^{\prime}=-\frac{b^{a}}{a^{2}}
$$

For if $P_{1} \equiv\left(x_{1}, y_{1}\right)$ and $P_{2} \equiv\left(-x_{1},-y_{1}\right)$ be the extremities of a diameter, and $P^{\prime \prime} \equiv\left(x^{\prime}, y^{\prime}\right)$ be any other point of the ellipse, and $m$ and m' the slopes of the chords $P^{P} P_{1}$ and $P^{2} P_{F}$ respectively,
thea

$$
m=\frac{y-y_{1}}{z-x_{1}} m^{\prime}=\frac{y+y_{1}}{z^{\prime}+x_{1}}
$$

therefore

$$
m m^{\prime}=\frac{y^{\prime 2}-y_{1}^{2}}{x^{2}-x_{2}^{3}}
$$

But
and

$$
\begin{aligned}
& \frac{x^{2}}{a^{3}} \div \frac{y^{2}}{b^{2}}=1 \\
& \frac{x_{1}^{2}}{a^{2}}+\frac{y_{1}^{2}}{b^{2}}=1 ;
\end{aligned}
$$

hence, by subtraction,

$$
\frac{x^{\prime 2}-x_{1}^{2}}{a^{3}}+\frac{y^{2}-y_{1}^{2}}{b^{2}}=0,
$$

that is,
hence

$$
\begin{aligned}
\frac{v^{\prime 2}-y_{1}^{2}}{a^{2}-x_{1}^{2}} & =-\frac{b^{2}}{a^{2}} \\
m m^{\prime} & =-\frac{b^{2}}{a^{2}}
\end{aligned}
$$

Therefore, supplemental chords are parallel to a pair of conjugate diameters.

For the special case when $a=b$, the product of the slopes becomes $m m^{\prime}=-1$, and therefore the supplemental chords are perpendicular; in other words, the angle inscribed in a semicircle is a right angle.
158. Equation of the ellipse referred to a pair of conjugate diameters.

In the simplest form for the equation of the ellipse, viz.,

$$
\begin{equation*}
\frac{x^{2}}{a^{2}}+\frac{y^{2}}{b^{2}}=1, \tag{1}
\end{equation*}
$$

the coorrdinate axes are the axes of the curve. These axes are conjugate diameters, and they are the only pair which are at right angles to each other (cf. Art. 155, $\beta$ ). It is desired now to find the equation of the curve referred to any pair of conjugate diameters, as $P_{2} P_{1}$ and $P_{2}^{\prime} P_{1}$, in Fig. 111. With the notation of Art. 154, let $\theta$ and $\theta$ be the angles the new $x$-axis, $C P_{1}$, and the new $y$-axis, $C P_{1}^{\prime}$, make with the old $x$-axis, respectively; they satisfy the relation [64],

$$
\begin{equation*}
\tan \theta \tan \theta=-\frac{b^{2}}{a^{2}} . \tag{2}
\end{equation*}
$$

The lengths of the conjugate semi-diameters are $a^{\prime}=C P_{1}$ and $V^{\prime}=C P_{1}^{\prime}$.

Then, by Art. 73, the equations for transformation to the new axes are

$$
\begin{equation*}
x=x^{\prime} \cos \theta+y^{\prime} \cos \theta, y=x^{\prime} \sin \theta+y^{\prime} \sin \theta, \tag{3}
\end{equation*}
$$

and after transformation equation (1) becomes

$$
\begin{gather*}
\left(\frac{\cos ^{2} \theta}{a^{2}}+\frac{\sin ^{2} \theta}{b^{2}}\right) x^{\prime 2}+2\left(\frac{\cos \theta \cos \theta^{\prime}}{a^{2}}+\frac{\sin \theta \sin \theta^{\prime}}{b^{\prime}}\right) x^{\prime} y^{\prime} \\
+\left(\frac{\cos ^{2} \theta}{a^{2}}+\frac{\sin ^{2} \theta}{b^{2}}\right) y^{\prime 2}=1 . \tag{4}
\end{gather*}
$$

But, by(2),

$$
\frac{\sin \theta \sin \theta}{\cos \theta \cos \theta}=-\frac{b^{2}}{a^{2}},
$$

hance

$$
\frac{\sin \theta \sin \theta}{b^{2}}+\frac{\cos \theta \cos \theta}{a^{2}}=0
$$

aned equation (4) reduces to

$$
\begin{equation*}
\left(\frac{\cos ^{2} \theta}{a^{3}}+\frac{\sin ^{3} \theta}{b^{3}}\right) x^{2}+\left(\frac{\cos ^{3} \theta}{a^{3}}+\frac{\sin ^{2} \theta}{b^{3}}\right) y^{2}=1 . . \tag{5}
\end{equation*}
$$

From equation (3) it in sesen that the curve is obliquely nymmetrical with respect to the beew ases. Moreover, alnce $\ddagger a^{\prime}$ atal $A V$ are the intercepte on the sew axes, equation (5) smay be further simplified:
for

$$
\begin{aligned}
& \left(\frac{\cos ^{2} \theta}{a^{2}}+\frac{\sin ^{2} \theta}{b^{3}}\right) a^{\prime 2}=1 \\
& \left(\frac{\cos ^{2} \theta}{a^{3}}+\frac{\sin ^{2} \theta}{b^{3}}\right) b^{\prime 2}=1
\end{aligned}
$$

म.ence

$$
\frac{\cos ^{2} \theta}{a^{2}}+\frac{\sin ^{2} \theta}{b^{2}}=\frac{1}{a^{23}} \cdot \frac{\cos ^{2} \theta}{a^{2}}+\frac{\sin ^{2} \theta}{b^{2}}=\frac{1}{b^{2}}
$$

and equation (5) may be written

$$
\begin{equation*}
\frac{x^{8}}{a^{3}}+\frac{y^{3}}{b^{2}}=1 . \tag{65}
\end{equation*}
$$

This is the required equation of the ellipee when refermed to any pair of conjugate diameters. It is evident that propositions which were derived for the standard form (1) withuut reference to the fact that the aves were revtangular, hold equally for equation [85] ; e.g., the equation of a tangont at the point $\left(x_{1}, y_{1}\right)$ of the curve is $\frac{x_{1} x}{a^{2}}+\frac{y_{1} y}{b^{2}}=1$.

Equation [65] states a geometric property of the ellipse entirely analogous to that of Art .112 . It is left to the student to express this property in words.

If the ellipse is referred to eyui-conjugnte diameters, so that $a^{\prime}=b^{\prime}$. its equation will be

$$
\begin{equation*}
x^{3}+y^{2}=a^{2} \tag{68}
\end{equation*}
$$

This is the same form as the simplest equation of the circle, but here the axem are obligue, and the equation represents, not a circle, but an ellijues.
159. Ellipse referred to conjugate diameters ; second method.

If the ellipeo

$$
\begin{equation*}
\frac{x^{3}}{a^{3}}+\frac{y^{8}}{y^{1}}=1 \tag{1}
\end{equation*}
$$

is transformed to a pair of conjugate diameters, its equation after transformation (Art. 78) must be of the form

$$
\begin{equation*}
A x^{3}+2 H x y+B y^{2}=1 \tag{2}
\end{equation*}
$$

But, since each chord parallel to either axis is bisected by the other, therefore, if $\left(x_{1}, y_{1}\right)$ is a point on the curve, then $\left(-x_{1},+y_{1}\right)$ must also be on the curve;
i.e., if $\quad A x_{1}^{2}+2 H x_{1} y_{1}+B y_{1}{ }^{2}=1$,
then $\quad A x_{1}{ }^{2}-2 H x_{1} y_{1}+B y_{1}{ }^{2}=1$,
and, cousequently,

$$
H=0
$$

Again, $\quad\left(a^{\prime}, 0\right)$ and $\left(0, b^{\prime}\right)$ are points on the curve;
hence

$$
A a^{\prime 2}=1, \quad B b^{\prime 2}=1 ;
$$

i.e.,

$$
A=\frac{1}{a^{\prime 2}}, \quad B=\frac{1}{b^{b^{2}}},
$$

therefore, equation (2) becomes

$$
\frac{x^{2}}{a^{\prime 3}}+\frac{y^{2}}{b^{\prime 3}}=1
$$

This method illustrates how analytic reasoning may often be used to shorten or perhaps obviate the algebraic reductions involved in a proof. With the similar methods of Arts. 39 and 40, it will suggest to the reader the power and interest of what are called the modern methods in analytic geometry.

## EXAMPLES ON CHAPTER X

1. Find the foci, directrices, eccentricity of the ellipse $4 x^{2}+3 y^{2}=5$.
2. Find the area of the ellipse $4 x^{2}+3 y^{2}=5$ (cf. Art. 151, Ex. 9).
3. Show that the polar of a point on a diameter is parallel to the conjugate diameter.
4. Find the equations of the normals at the ends of the latus rectum, and prove that each passes through the end of a minor axis if $e^{4}+e^{2}=1$.
5. Show that the four lines from the foci to two points $P_{1}$ and $P_{2}$ on an ellipse all touch a circle whose center is the pole of $P_{1} P_{8}$.
6. Tangents are drawn from the point $(3,2)$ to the ellipse

$$
x^{2}+4 y^{2}=4
$$

Find the equation of the line joining $(3,2)$ to the middle point of the chord of contact.
7. Find the locus of the center of a circle which passes through the point $(0,3)$ and touches internally the circle $x^{2}+y^{2}=25$.
8. Find the length of the major axis of an ellipse whose minor axis is 10 , and whose area is equal to that of a circle whose radius is 8.
9. The minor axls of an ellipse is 6 , and the sum of the foral radii for a certain peint on the curve in 16; find its major axis, dastance betweens foci, and area.
10. A line of fixed length moves so that its ends remain in the coordinato axes; find tho locus generated by any point of the lime.
11. Find the loevs of the middle prints of chorids of an ellipwe drawn through the ponitive end of the minor axis.
12. With a given focus and directrix a series of ellipses are drawn: show that the locus of the extremities of their minor axes in a parabola.
13. Show that the line $x \cos a+y \sin a=p$ touches the ellipse
if

$$
\begin{gathered}
\frac{2^{3}}{a^{3}}+\frac{y^{2}}{b^{3}}=1 \\
p^{2}=a^{8} \cos ^{8} a+b^{8} \sin ^{2} a
\end{gathered}
$$

14. Find the locus of the foot of the perpendicular drawn from the center of the ellipse $\frac{x^{2}}{a^{2}}+\frac{y^{3}}{b^{3}}=1$ to a variable tangent.
15. Prove, amalytically, that if the normals to an ellipme pans through its center, the ellipse is a circle.
16. Find the locus of the vertex of a triangle of base $2 a$, and such that the product of the tangents of the angles at its base is $\frac{\mathrm{l}^{3}}{\mathrm{c}^{3}}$.
17. The ratio of the subnormals for corresponding points on the ellipso and major auxiliary circle is $\frac{b^{3}}{a^{8}}$
18. Find the equation of the ellipse $9 x^{3}+25 y^{3}=225$ when referred to its equi-conjugate diameters.
19. Normals at corresponding points on the ellipee, and on the major auxiliary circle, meet on the circle $x^{3}+y^{3}=(a+b)^{2}$.
20. Two tangents to an ellipse are perpendicular to each other; find the locus of the middle point of their chord of contact.
21. If $P_{1}$ is a point on the director circle, the promluct of the distances of the center and the prole, respectively, from its prolar with respect to the ellipse is constant.

The tangents drawn from the point $P$ to an ellipse make angles $\theta_{1}$ and $\theta_{2}$ with the major axis; find the locus of $P$
22. when $\theta_{1}+\theta_{2}=2 a$ a constant.
23. when $\tan \theta_{1}+\tan \theta_{3}=c$, a constant.

Find the locus of the intersection $P$ of two tangents
24. if the sum of the eccentric angles of their points of contact is a constant, equal to $2 a$.
25. if the difference of the eccentric angles be $120^{\circ}$.
26. Find the locus of the middle points of chords of an ellipse which pass through a given point ( $h, k$ ).
27. Find the tangents common to the ellipse $\frac{x^{2}}{a^{2}}+\frac{y^{3}}{b^{2}}=1$ and its midcircle $x^{2}+y^{2}=a b$.

## CHAPTER XI

## The Hyperbola, $\frac{x^{2}}{a^{2}}-\frac{v^{2}}{b^{2}}=1$

160. Review. The definition of the hyperbola given in Chapter VIII led at once to two standard forms for its equation, viz. (ef. Arts, 116, 118):

$$
\frac{x^{2}}{a^{2}}-\frac{y^{2}}{b^{2}}=1,
$$

when the axes of the curve are coincident with the coobrdinate axes ; and

$$
\frac{(x-h)^{2}}{a^{2}}-\frac{(y-k)^{2}}{b^{2}}=1
$$

when the axes of the curve are parallel to the coordinate axes, and its center is the point ( $h, k$ ).
A brief discussion of the first standard form $\frac{x^{2}}{x^{3}}-\frac{y^{3}}{l^{2}}=1$ showed that the curve has its eccentricity given by the relation $b^{2}=a^{2}\left(b^{3}-1\right)$, i.e., by $a^{2}=\frac{a^{2}+b^{2}}{a^{2}}$; its foei are the two points ( $\pm a e, 0$ ), and its directrices the lines $x= \pm \frac{a}{e}$ (Art. 116). These results are entirely analogous to the corresponding ones for the ellipse, if it be remembered that $1-e^{2}$ is positive for the ellipse, while $\alpha^{3}-1$ is positive for the hyperbola.
The similarity of the equations of the hyperbola and the ellipse leads to various correspomlences in the analytic properties of the curves. For example, the equation

$$
\frac{x_{1} x}{a^{2}}-\frac{y_{1} y}{b^{2}}=1
$$

represents the polar of the point $\left(x_{1}, y_{1}\right)$ with respect to the hyperbola ; it represents the chord of contact if the point is outside the hyperbola, and the tangent if the point is upon the curve (Arts. 126, 122). Again, by the method shown in Art. 143, merely replacing $b^{2}$ by $-b^{2}$, it is evident that

$$
\begin{equation*}
y=m x \pm \sqrt{a^{2} m^{2}-b^{2}} \tag{17}
\end{equation*}
$$

is the equation of a tangent to the hyperbola in terms of its slope $m$. The student will be able in like manner to prove other properties of the hyperbola, analogous to those already shown for the ellipse, using the same methods of derivation.

It was shown, however, in the discussion of Chapter VIII, as also in Art. 48, that the nature of the hyperbola apparently differs widely from that of the ellipse, consisting, as it does, of two open infinite branches instead of one closed oval. It is desired in the present chapter to show some of the most important properties of the hyperbola which correspond to similar properties in the ellipse; and also to prove some special properties which are peculiar to the hyperbola. For the most part, these will be derived for the hyperbola $\frac{x^{2}}{a^{2}}-\frac{y^{2}}{b^{2}}=1$; and the facts summarized above will be assumed.
161. The difference between the focal distances of any point on an hyperbola is constant ; it is equal to the transverse axis.

The hyperbola $\frac{x^{2}}{a^{2}}-\frac{y^{2}}{b^{2}}=1$ has its foci at the points $F_{1} \equiv(-a e, 0), F_{2} \equiv(a e, 0)$, with $b^{2}=a^{2} e^{2}-a^{2}$.

Let $P_{1} \equiv\left(x_{1}, y_{1}\right)$ be any given point on the curve, so that

$$
y_{1}^{2}=\frac{b^{2} x_{1}^{2}}{a^{2}}-b^{2}
$$

Then $F_{1} \mu_{1}^{3}=\left(x_{1}+a e\right)^{2}+y_{1}{ }^{2}=x_{1}{ }^{2}+2 a e x_{1}+a^{2} e^{2}+y_{1}{ }^{3}$

$$
\begin{aligned}
& =a^{2} c^{2}+2 a e x_{1}+\frac{b^{2}+a^{2}}{a^{2}} x_{1}^{2}-b^{2} \\
& =a^{2} e^{2}+2 a e x_{1}+c^{2} x_{1}^{2}+a^{2}-a^{2} e^{2} \\
& =\varepsilon^{2} x_{1}^{2}+2 a e x_{1}+a^{2},
\end{aligned}
$$

i.e.,

$$
\begin{equation*}
F_{1} P_{1}=e x_{1}+a \tag{1}
\end{equation*}
$$

Similarly,

$$
\begin{equation*}
F_{3} P_{1}=x_{1}-a . \tag{2}
\end{equation*}
$$

These expressions for the focal distances of a point on the hyperbola are of the same form as those for the ellipse (Art. 144); here, however, $e>1$.

Subtracting equation (2) from equation (1) gives

$$
F_{1} P_{1}-F_{2} P_{1}=2 a ;
$$

hence, the difference between the focal distances of any point on an hyperbola is constant; it is equal to the transeerse axis.

If the foci are not given, they may be constructed as follows, provided the semi-axes of the curve are known : plot the points $A \equiv(a, 0)$ and $B \equiv(0, b)$; then with the center of the hyperbola as center, and the distance $A B$ as radius, describe a circle; it will cut the transverse axis in the required foci $F_{1}$ and $F_{9}$, for

$$
A B=\sqrt{a^{2}+b^{2}}=\sqrt{a^{2} c^{3}}= \pm a e .
$$

162. Construction of the hyperbola. The property of the precerling article might be taken as a new definition of the hyperbola, viz. : the hyperbola is the locus of a point the dif. ference of whose distances from two fixed points is constant. This definition leads at once to the equation of the curve (ef. Ex. 6, p. 67 ), and also to a method for its construction.
(a) Construction by separate points. Let $A^{\prime} A$ be the given difference of the focal distances, - i.e., the transverse axis of the hyperbola, - and $\boldsymbol{F}_{1}$ and $\boldsymbol{F}_{2}$ the given fixed points, the foci. With either

 focus, say $\boldsymbol{F}_{1}$, as a center, and a radius $A^{\prime} R>A^{\prime} A$, $P_{1} \cdots \cdots \cdots \ddot{F}_{1}$ describe an are; then
Fia. 118.
 with the other focus as a center, and a radius $A R$ describe an are cutting the first ares in the two points $\boldsymbol{P}_{1}$. These are points of the hyperbola. Similarly, as many points as desired may be obtained and then connected by a smooth curve, - approximately an hyperbola.
( $\beta$ ) Construction by a continuously moving point; the foci being given. Pivot a straight edge $L M$ at one focus $F_{1}$, so that $F_{1} M$ is greater than the transverse axis $2 a$; at $M$ and the other focus $F_{3}$ fasten the ends of a string of length $l$, such that $F_{1} M=l+2 a$; then a pencil $\boldsymbol{P}$ held against the string and straight edge (see Fig. 114), so as to keep the string always taut, will, while the straight edge revolves about $F_{1}$, trace one branch of the hyperbola. By fastening the string at the first focus and the straight edge at the second, the other branch of the curve can be traced.
163. The tangent and normal bisect internally and externally the angles between the focal radii of the point of contact.

Let $\boldsymbol{F}_{1}$ and $\boldsymbol{F}_{2}$ be the foci of the hyperbola $\frac{x^{2}}{a^{2}}-\frac{y^{2}}{b^{2}}=1$, $P_{1} T$ the tangent, and $P_{1} N$ the normal at the point $\boldsymbol{P}_{\mathbf{1}} \equiv\left(x_{1}, y_{1}\right)$.

Then the equation of $P_{1} T$ is $\frac{x_{1} x}{a^{2}}-\frac{y_{1} y}{b^{2}}=1$, and the leugth of the intercept $O T$ of the tangent is

$$
O T=\frac{a^{2}}{x_{1}}
$$

Now, in the triangle $\boldsymbol{F}_{1} P_{1} \boldsymbol{F}_{8}$
and

$$
\begin{aligned}
F_{1} T & =F_{1} O+O T=a e+\frac{a^{3}}{x_{1}} \\
& =\frac{a}{x_{1}}\left(e x_{1}+a\right)
\end{aligned}
$$

$$
\begin{aligned}
T F_{3} & =O F_{3}-O T=a e-\frac{a^{2}}{x_{1}} \\
& =\frac{a}{x_{1}}\left(e x_{1}-a\right)
\end{aligned}
$$

but

$$
\begin{equation*}
F_{1} P_{1}=e x_{1}+a_{3} \tag{Art.161}
\end{equation*}
$$

and

$$
P_{1} F_{2}=e x_{1}-a
$$

Hence

$$
F_{1} T: T F_{2}=F_{1} P_{1}: P_{1} F_{2}
$$

and, by elementary geometry, the tangent bisects internally the angle between the focal radii. Then, since the normal is [xpendicular to the tangent. the normal $P_{1} N$ bisects the external angle $F_{2} P_{1} W$. These facts suggest a method, anal-
ogous to that of Art. 148, for constructing the tangent and normal to an lyyperbola at a given point.
164. Conjugate hyperbolas. A curve bearing very close relations to the hyperbola

$$
\begin{equation*}
\frac{x^{2}}{a^{2}}-\frac{y^{2}}{l^{2}}=1 \tag{1}
\end{equation*}
$$

is that represented by the equation
i.e., by

$$
\begin{align*}
& \frac{y^{2}}{b^{2}}-\frac{x^{2}}{a^{2}}=1 \\
& \frac{x^{2}}{a^{2}}-\frac{y^{2}}{b^{2}}=-1 \tag{2}
\end{align*}
$$

Fic. 116.
in which $a$ and $b$ have the same values as in equation (1). This curve is evidently an hyperbola, and has for its transverse and conjugate axes, respectively, the conjugate and transverse axes of the original, or primary hyperbola. Two such hyperbolas are called conjugate hyperbolas ; they are sometimes spoken of as the $x$ - and $y$-hyperbolas, respectively.

It follows at once that the liypertrola (2), conjugate to the hyperbola (1), has for its eccentricity

$$
e^{\prime}=\frac{\sqrt{a^{2}+b^{3}}}{b}
$$

for foci the points $\left(0, \pm b e^{\prime}\right)$, and for directrices the lines

$$
y= \pm \frac{8}{9}
$$

Two conjugate hyperbolas have a common center, and their foci are all at the common distance $\sqrt{a^{2}+b^{2}}$ from this center; i.e., the foci all lie on a circle about the center, having for radius the semi-diagonal OS of the rectangle ujon their common axes, and whose sides are tangent to the curves at their vertices. Moreover, when the curves are constructed it will be found that they do not interseet, but are separated by the extended diagonals $O S^{\prime}$ and $O K$ of this cireumscribed rectangle, which they approach from opposite sides. These diagonals are examples of a class of lines of great interest in analytic theory; they are calleal axymptotes (ef. Art. 165, also Art. 37, (5)).

## EXERCISES

1. Construct an hyperbola, given the distance between its foei as 3 cm . and $e=2$.
2. Construet an hyperbola, given the dintance from directrix to focus as 2 cm . How many such hypertiolas are prosible?
3. Write the equation of an hypertola conjugate to the hyperbola $9 x^{3}-16 y^{2}=144$, and find its axes, foeci, and latus rectum. Sketch the figure.
4. Write the equations of the tangent and normal to the hyperhola $18 x^{2}-9 y^{2}=112$ at the point ( 4,4 ), and find the subtangent and subnermal.
5. Write the equations of the polars of the point (3, 1) with respect to the hyperkola $9 x^{3}-16 y^{8}=14$ and its conjugate, respectively.
6. For what points of an hyperbola are the subtangent and subnormal equal ?
7. Given the hyperbola $9 y^{2}-4 x^{2}=36$, find the focal radii of the point whose ordinate is ( 4 ), and abscissa positive.
8. A tangent which is parallel to the line $5 x-4 y+7=0$, is drawn to the hyperbola $x^{2}-y^{2}=9$; what is the subnormal for the point of contact?
9. What tangent to the hyperbola $\frac{x^{2}}{10}-\frac{y^{2}}{12}=1$ has its $y$-intercept 2 ?
10. Find, by equation [67], the two tangents to the hyperbola $4 x^{2}-2 y^{2}=6$ which are drawn through the point $(3,5)$.
11. Find the polars of the vertices of an hyperbola with respect to its conjugate hyperbola.
12. Prove that if the crack of a rifle and the thud of the ball on the target are heard at the same instant, the locus of the hearer is an hyperbola.
13. An ellipse and hyperbola have the same axes. Show that the polar of any point on either curve is a tangent to the other.
14. Find the equation of an hyperbola whose vertex bisects the distance from the focus to the center.
15. If $e$ and $e^{\prime}$ are the eccentricities of an hyperbola and its conjugate, then

$$
e^{2}+e^{\prime 2}=e^{2} e^{\prime 2}
$$

16. If $e$ and $e^{\prime}$ are the eccentricities of two conjugate hyperholas, then

$$
a e=b e^{\prime} .
$$

17. Find the eccentricity and latus rectum of the hyperhola

$$
y^{2}=4\left(x^{2}+a^{2}\right)
$$

18. Find the tangents to the hyperbola $3 x^{2}-16 y^{2}=144$, which, with the tangent at the vertex, form a circumscribed equilateral triangle. Find the area of the triangle.
19. Find the lengths of the tangent, normal, subtangent, and sulnormal for the point $(3,2)$ of the hyperbola $x^{2}-2 y^{2}=1$.
20. Asymptotes. If a tangent to an infinite branch of a curve approaches more and more closely to a fixed straight line as a limiting position, when the point of contact moves further and further away on the curve and becomes infinitely
diatant, then the fixed line is called an asymptote of the curve. More briefly, though less accurately, this definition may be stated as follows: an asymptote to a curvo is a tangent whose point of contact is at infinity, but which is not itself entirely at infinity. It is evident that to have an asymptwe a curve must have an infiwite branch; and this branch may be considered as having iwo coincident, and infinitely distant, points of intersection with its asymptote. This property will aid in obtaining the equation of the asymptote.

The hyperbola

$$
\begin{equation*}
\frac{x^{2}}{a^{2}}-\frac{y^{2}}{b^{2}}=1, \tag{1}
\end{equation*}
$$

Fio. 118
is ent by the line

$$
\begin{equation*}
y=m x+c \tag{2}
\end{equation*}
$$

in two points whoso abscissas are given by the equation

$$
\begin{equation*}
\left(a^{2} m^{2}-b^{2}\right) x^{2}+2 a^{2} c m x+a^{2} b^{2}+a^{2} c^{2}=0 . \tag{8}
\end{equation*}
$$

If line (2) is an asymptote, the two roots of equation must both become infinite; therefore, by Art. 10,

$$
\begin{gathered}
a^{2} m^{2}-b^{2}=0 \text { and } 2 a^{2} c m=0, \\
\quad 0=0 \text { and } m= \pm \frac{b}{a}
\end{gathered}
$$

Sulstituting these values in equation (2), gives

$$
\begin{equation*}
y=\frac{b}{a} x, \text { and } y=-\frac{b}{a} x \tag{5}
\end{equation*}
$$

[^39]and these equacions represent the asymptotes of the hyperbrola; they are the lines $O S$ and $O K$ in Fig. 117. Therefore, the hyperbola has two asymptotes; they pass through its center, and are the diagonals of the rectangle described upon its axes.

Since the equation of the hyperbola conjugate to (1) is

$$
\begin{equation*}
\frac{x^{2}}{a^{2}}-\frac{y^{2}}{b^{2}}=-1, \tag{6}
\end{equation*}
$$

and thus differs from equation (1) only in the sign of the second member, which affects only the constant term in equation (3), therefore the equations (4) determine the value of $m$ and $c$ for the asymptotes of the conjugate hyperbola also. It follows that conjugate hyperbolas have the same asymptotes.

A second derivation of the equation of the asymptotes of an hyperbola (1) is as follows :

The equation of the tangent to (1) at the point $\left(x_{1}, y_{1}\right)$ is

$$
\begin{equation*}
\frac{x_{1} x}{a^{2}}-\frac{y_{1} y}{b^{2}}=1, \quad . \quad . \tag{7}
\end{equation*}
$$

which may be written in the form

$$
\begin{equation*}
b^{2} x=a^{2} y \frac{y_{1}}{x_{1}}+\frac{a^{2} b^{2}}{x_{1}} \tag{8}
\end{equation*}
$$

Since $\left(x_{1}, y_{1}\right)$ is on the curve (1),
therefore $\quad \frac{x_{1}{ }^{2}}{a^{2}}-\frac{y_{1}{ }^{2}}{b^{2}}=1$, i.e., $\frac{y_{1}}{x_{1}}=\sqrt{\frac{b^{2}}{a^{2}}-\frac{b^{2}}{x^{2}}}$
Substituting this value of $\frac{y_{1}}{x_{1}}$ in equation (8), it becomes

$$
\begin{equation*}
b^{2} x=a^{2} y \sqrt{\frac{b^{2}}{a^{2}}-\frac{b^{2}}{x_{1}}}+\frac{a^{2} b^{2}}{x_{1}}, \tag{10}
\end{equation*}
$$

which is only another form of the equation of the tangent represented by equations ( $\overline{7}$ ) or (8). If now the point of contact $\left(x_{1}, y_{1}\right)$ moves further and further away, so that $x_{1} \doteq \infty$, then the limiting position of the line (10) is represented by $b^{2} x=a^{2} y\left( \pm \frac{b}{a}\right)= \pm a b y$.
Hence the equations of the asymptotes are: $y= \pm \frac{b}{a} x$ (cf. Art. 156).

The equations of the asymptotes may be combined, by Irt. 40, into the one equation which represents both lines, viz.:

$$
\begin{equation*}
\frac{x^{2}}{a^{2}}-\frac{v^{2}}{b^{2}}=0 . \tag{68}
\end{equation*}
$$

166. Relation between conjugate hyperbolas and their asymptotes. It has been seen that the standard forms for the equations of the primary hyperbola, its asymptotes, and its conjugate hyperbola are, respectively,

$$
\begin{align*}
& \frac{x^{2}}{a^{3}}-\frac{y^{2}}{b^{3}}=1,  \tag{1}\\
& \frac{x^{2}}{a^{2}}-\frac{y^{2}}{b^{2}}=0,  \tag{2}\\
& \frac{x^{2}}{a^{2}}-\frac{y^{2}}{b^{2}}=-1 . \quad . \quad . \tag{8}
\end{align*}
$$

It will be noticed at once that these three equations differ only in their constant terms; and that the equation of the primary hyperbola (1) differs from that of the asymptotes (2) by the negative of the constant by which the equation of the conjugate hyperbola (3) differs from equation (2). Moreover, this relation between the equations of the three boci must hold when not in their standard forms, i.e.. whatever the coördinate axes. For, any transformation of coördinates will affect only the first member of equations (1). (2), and (3), and will affect these in precisely the same way. After the transformation, therefore, the equations of the loci will differ only by a constant (not, however, usually by 1): and the value of the constant in the equation of the asymptotes will be milway between the values of the constants in the equations of the two hyprerbolas.

Example 1. An hyperbola having the lines

$$
\text { (1) } x+2 y+3=0 \text { and (2) } 3 x+4 y+5=0
$$

for asymptotes, will have an equation of the form

$$
\begin{equation*}
(x+2 y+3)(3 x+4 y+5)+k=0 \tag{3}
\end{equation*}
$$

while the equation of its conjugate hyperbola will be

$$
\begin{equation*}
(x+2 y+3)(3 x+4 y+5)-k=0 \tag{4}
\end{equation*}
$$

If a second condition is imposed upon the hyperbola, e.g., that it shall pass through the point $(1,-1)$, then the value of $k$ may be easily found thus: since the curve passes through the point ( $1,-1$ ), therefore by equation (3),

$$
(1-2+3)(3-4+5)+k=0 ; \therefore k=-8
$$

and the equation of the hyperbola is

$$
\begin{array}{ll} 
& (x+2 y+3)(3 x+4 y+5)-8=0 \\
\text { that is, } \quad & 3 x^{2}+10 x y+8 y^{2}+14 x+22 y+7=0 \tag{5}
\end{array}
$$

and the equation of the conjugate hyperbola is

$$
3 x^{2}+10 x y+8 y^{2}+14 x+22 y+23=0
$$

Example 2. The equation of the asymptotes of the hyperbola

$$
\begin{equation*}
3 x^{2}-14 x y-5 y^{2}+7 x+13 y-8=0 \tag{1}
\end{equation*}
$$

differs from equation (1) by a constant only, hence it is of the form

$$
\begin{equation*}
3 x^{2}-14 x y-5 y^{2}+7 x+13 y+k=0 \tag{2}
\end{equation*}
$$

Now equation (2) represents a pair of straight lines, therefore its first member can be factored, and, by Art. 67, [17]
i.e., $\quad 64 k=-384$, whence $k=-6$.

Therefore the equation of the asymptotes is

$$
3 x^{2}-14 x y-5 y^{2}+7 x+13 y-6=0
$$

i.e., $\quad(3 x+y-2)(x-5 y+3)=0$;
and the equation of the conjugate hyperbola is

$$
3 x^{3}-14 x y-5 y^{2}+7 x+13 y-4=0 .
$$

167. Equilateral or rectangular hyperbola. If the axes of an hyperbola are equal, so that $a=b$, its equation has the form

$$
\begin{equation*}
x^{2}-y^{2}=a^{2} \text {, } \tag{1}
\end{equation*}
$$

and its cecentricity $0=\sqrt{2}$. Its conjugate hyperbola has the equation

$$
\begin{equation*}
x^{2}-y^{2}=-x^{2} ; \tag{2}
\end{equation*}
$$

with the same cecentricity and the same shape; while its asymptotes have the equations

$$
\begin{equation*}
x= \pm y, \tag{3}
\end{equation*}
$$

and are therefore the bisectors of the angles formed by the axes of the curves; hence the asymptotes of these hyperbolas are perpendicular to each other. The hyperbola whose axes are equal is therefore called an equilateral, or a rectangular hyperbola, aceording as it is thunght of as having equal axes or asymptotes at right angles.

## EXERCISES

1. Find the asymptotes of the hyperbola $9 x^{2}-16 y^{3}=25$, and the angle between them.
2. Where are the proles of the asymptotes of the hypurtwola

$$
9 x^{4}-16 y^{4}=25
$$

with reference to the ourve?
3. If the vertex lies two thirds of the distance from the cinter to the focus, find the equations of the hyperbola, and of its asyupptotes.
4. If a line $y=m z+c$ meets the hyperloila $\frac{x^{3}}{a^{3}}-\frac{y^{3}}{b^{2}}=1$ in one finite and one infinitely distant point, the line is parallel to an anymptente.
5. Shew that, in an equilateral hypuerlmela, the dostance of a point from the eventer is a mean propertional between its focal distances.
6. Find the equation of the hypertwola passing through the point $(0,7)$, and having for asymptotes the lines

$$
2 x-v=7, \text { and } 3 x+3 y=5 \text { (cf. Art. 16ef). }
$$

7. Write the equation of the hyperbola conjugate to that of Ex. 6.
8. Find the equations of the asymptotes of the hyperbola

$$
2 x^{3}-x y-2 x=y^{2}+y+6 ;
$$

also find the equation of the conjugate hyperbola.
9. Find the equation of the asymptotes of the hyperhola

$$
3 x^{2}+34 x y+11 y^{2}-x+21 y=0
$$

10. Find the equation of the hyperbola conjugate to

$$
9 x^{2}-16 y^{2}+36 x+160 y=508
$$

11. Prove that a perpendicular from the focus to an asymptote of an hyperbola is equal to the semi-conjugate axis.
12. The asymptotes meet the directrices of the $x$-hyperbola on the $x$-auxiliary circle, and of the conjugate hyperbola on the $y$-auxiliary circle.
13. The circle described about a focus, with a radius equal to half the conjugate axis, will pass through the intersections of the asymptotes and a directrix.
14. The line from the center $C$ to the focus $F$ of an hyperbola is the diameter of a circle that cuts an asymptote at $P$; show that the chords $C P$ and $F P$ are equal, respectively, to the semi-transverse and semiconjugate axes.
15. The hyperbola referred to its asymptotes. If the asymptotes of an hyperbola are chosen as the coördinate axes, their equations will be $x=0$ and $y=0$, respectively ; or, combined in one equation,

$$
\begin{equation*}
x y=0 \tag{1}
\end{equation*}
$$

By the reasoning of Art. 166, it follows that the equation of the hyperbola, - which differs from that of its asymptotes by a constant, - is

$$
\begin{equation*}
x y=k \tag{2}
\end{equation*}
$$

wherein the value of the constant $k$ is to be determined liy an additional assigned condition concerning the curve ; e.g., that it shall pass through a given point.

The value of this constant, in terms of $a$ and $b$, can in general be found most easily by making the proper trannformation of coürdinates upon the equation of the hyperbola

$$
\begin{equation*}
\frac{x^{2}}{a^{2}}-\frac{y^{2}}{b^{2}}=1 \tag{8}
\end{equation*}
$$

Fio.14s.
The new $x$-axis makes the angle $\theta$, the new $y$-axis the angle $\theta^{\prime}$, with the old $x$-axis, such that

$$
\tan \theta=-\frac{b}{a}, \tan \theta^{\prime}=\frac{b}{a}
$$

Hence

$$
\sin \theta=-\sin \theta^{\prime}=\frac{-b}{\sqrt{a^{2}+b^{3}}}
$$

and

$$
\cos \theta=+\cos \theta^{\prime}=\frac{a}{\sqrt{a^{2}+b^{2}}}
$$

therefore the formulas [25] for transformation,

$$
x=x^{\prime} \cos \theta+y^{\prime} \cos \theta^{\prime}, \quad y=x^{\prime} \sin \theta+y^{\prime} \sin \theta^{\prime},
$$

trecome in this case

$$
\begin{equation*}
x=\frac{a}{\sqrt{a^{2}+b^{2}}}\left(x^{\prime}+y^{\prime}\right), \quad y=\frac{-b}{\sqrt{a^{2}+b^{2}}}\left(x^{\prime}-y^{\prime}\right) . \tag{4}
\end{equation*}
$$

Applying this transformation, equation (3) becomes

$$
\frac{x^{\prime 2}+2 x^{\prime} y^{\prime}+y^{\prime 2}}{a^{2}+b^{2}}-\frac{x^{\prime 2}-2 x^{\prime} y^{\prime}+y^{\prime 2}}{a^{2}+b^{2}}=1 ;
$$

that is, dropping the accents,

$$
\begin{equation*}
x y=\frac{a^{2}+b^{2}}{4} \tag{69}
\end{equation*}
$$

which is the desired equation of the hyperbola when referred to its asymptotes as coördinate axes.

The equation of the conjugate hyperbola is then

$$
\begin{equation*}
x y=-\frac{a^{2}+b^{2}}{4} \tag{5}
\end{equation*}
$$

Remembering the relation $b^{2}=a^{2}\left(e^{2}-1\right)$, it will be seen that the value of the constant term in equation (2) may be written

$$
k=\frac{a^{2}+b^{2}}{4}=\frac{a^{2} e^{2}}{4}=c^{2}
$$

so that $c$ is half the distance of the focus from the center of the curve. Again, the coördinates of the foci, $x= \pm a e, y=0$, become after the transformation (4),

$$
\begin{equation*}
x=y= \pm \frac{a^{2}+b^{2}}{2} \frac{a}{a} \tag{6}
\end{equation*}
$$

and the equations of the directrices, $x= \pm \frac{a}{e}$, become

$$
\begin{equation*}
x+y= \pm a \tag{7}
\end{equation*}
$$

169. The tangent to the hyperbola $x y=c^{2}$. The equation of the tangent to the hyperbola

$$
\begin{equation*}
x y=c^{2} \tag{1}
\end{equation*}
$$

at any given point ( $x_{1}, y_{1}$ ), may be easily derived by the secant method (cf. Arts. 84, 122). Let $P_{1} \equiv\left(x_{1}, y_{1}\right)$ and $P_{2} \equiv\left(x_{2}, y_{2}\right)$ be two points on the curve; then

$$
\begin{equation*}
x_{1} y_{1}=c^{2}, \quad . \quad . \quad \text { (2) and } x_{2} y_{2}=c^{2} \tag{3}
\end{equation*}
$$

Then crguation of the lime through $P_{1}$ and $P_{3}$ is

$$
y-y_{1}=\frac{y_{2}-y_{1}}{x_{3}-x_{1}}\left(r-x_{1}\right)
$$

wherein $\frac{y_{2}-y_{1}}{x_{2}-x_{1}}$ must have a value determined by equations (2) and (8), hence

$$
m=\frac{\frac{c^{2}}{x_{3}}-\frac{c^{2}}{x_{1}}}{x_{3}-x_{1}}=\frac{e^{2}}{x_{1} x_{3}} \cdot x_{1}-x_{2}=-\frac{c_{1}}{x_{1}-x_{1}} .
$$

The equation of the secant line $P_{1} P_{2}$ is therefore

$$
\begin{equation*}
y-y_{1}=-\frac{c^{2}}{x_{1} x_{3}}\left(x-x_{1}\right) . \tag{4}
\end{equation*}
$$

If now the point $P_{3}$ becomes coincident with $P_{3}$, equation (4) becomes

$$
y-y_{1}=-\frac{c^{2}}{x_{1}^{2}}\left(x-x_{1}\right)
$$

which may be reduced by equation (2) to

$$
\begin{equation*}
\frac{x}{x_{1}}+\frac{y}{y_{1}}=2 \tag{70}
\end{equation*}
$$

or to

$$
y_{1} x+x_{2} y=2 \sigma^{2}
$$

which is the required equation of the tangent at the point $I_{1}=\left(x_{1}, y_{1}\right)$ of the curve.
170. Geometric properties of the hyperbola. Equation [69] states the following intrinsio property for the hyperbola, $P_{1}=\left(x_{1}, y_{1}\right)$ being any point on the curve (Fig. 119).

$$
4 M P_{1} \cdot L P_{1}=O F^{\mu}
$$

that is, for every point of the hyperbala, four times the product of its distances from the asymptotes, measured parallel to the asymptotes respectively, is equal to the square of the distance from the center to the foews; and is therefore constant.

Again, $2 \theta$ being the angle between the asymptotes, equation [69] may be written

$$
\begin{equation*}
x y \sin 2 \theta=\frac{\sqrt{a^{2}+b^{2}}}{2} \frac{\sqrt{a^{2}+b^{2}}}{2} \sin 2 \theta \tag{1}
\end{equation*}
$$

Fra. 119.
Now $x y \sin 2 \theta$ is the area of the parallelogram $O M P_{1} L$, constructed upon the coördinates of the point $P_{1}$ of the hyperbola; and since the coördinates of the vertex $A$ are $x=y=\frac{\sqrt{a^{2}+b^{2}}}{2}$, the second member of equation (1) is the area of the rhombus $O R A S$, constructed upon the coördinates of the vertex. Therefore, the area of the parallelogram formed by the asymptotes and lines parallel to them drawn from any point of an hyperbola, is constant; it is equal to the rhombus similarly drawn from the vertex of the curve.

The equation of the tangent to the hyperbola

$$
\begin{equation*}
x y=c^{2} \tag{2}
\end{equation*}
$$

at the point $P$, is

$$
\begin{equation*}
\frac{x}{x_{1}}+\frac{y}{y_{1}}=2 \tag{3}
\end{equation*}
$$

The $x$-intercept of this tangent is $O T=2 x_{1}$; hence if $O T^{\prime \prime}$ be the $y$-intercept, and $M$ the foot of the ordinate of $P_{1}$, then from the similar triangles $M T P_{1}$ and $O T T^{\prime}$,

$$
T P_{1}: T T^{\prime \prime}=M T: O T=x_{1}: 2 x_{1}=1: 2
$$

Hence, the segment of any tangent to an hyperhola between the asymptotes in bisected by the point of contact.

The tangent (3) has the intercepts on the $x$-axis and $y$-axis, respectively.

Then

$$
O T=2 x_{1}, \quad O T^{\prime \prime}=2 y_{1^{\circ}}
$$

But since $\left(x_{1}, y_{1}\right)$ is a proint of the hyperbola

$$
\begin{gather*}
4 x_{1} y_{1}=a^{2}+b^{3} \\
O T \cdot O T=a^{2}+b^{2} \tag{5}
\end{gather*}
$$

i.e., the rectangle formed by the intercepts which any tangent to the hyperbola makes upon the asymptotes is constant; it is equal to the sum of the squar s upon the semi-axe.

Moreover, equation (5) m y b written

$$
\begin{equation*}
O T \cdot O T^{\prime} \frac{\sin 2 \theta}{2}=\frac{a^{-}+k^{2}}{2} \sin 2 \theta ; \tag{6}
\end{equation*}
$$

but $\sin 2 \theta=2 \sin \theta \cos \theta=2 \frac{b}{\sqrt{a^{2}+b^{2}}} \frac{a}{\sqrt{a^{2}+b^{2}}}=\frac{2 a b}{a^{2}+b^{2}}$
hence (6) bcomes $\frac{O T \cdot O T^{\prime \prime}}{2} \sin 2 \theta=a b$;
that is, the triangle formed by any $t$ ngent to an hyperbola and its asymptotes is constant; it is equal to the rectangle upon the semi-axes.

## EXERC'SES

1. Find the equation of the hyperbola $9 x^{3}-16 y^{9}=25$ when neferred to its eaymptotes as axes.
2. Find the semi-axes, eccentricity, and the vertices, of the liyperbola $x y=4$, the angle between the axes (asymptotes) being $00^{\circ}$.
3. Find the semi-axes, ecoentricity, vertines, and the foei, of the hyperbola $s y=-12$, the angle hetween the axes lwing bir.
4. Prove that the segments of any line which are intercepted between an byperbola and its asymptotes are equal.
5. Express the angle between the asymptotes of an hyperbola in terms of $e$; i.c., in terms of the eccentricity of the hyperbola.
6. The segment of a tangent to an hyperbola intercepted by the conjugate hyperbola is bisected at the point of contact.
7. Show that the pole of any tangent to the rectangular hyperbola $x y=c^{2}$, with respect to the circle $x^{2}+y^{2}=a^{2}$, lies on a concentric and similarly placed rectangular hyperbola.
8. Prove that the asymptotes of the hyperbola $x y=h x+k y$ are $x=k$, and $y=h$.
9. Derive the equation of the tangent to the curve $x y=k x+k y$ at the point $P \equiv\left(x_{1}, y_{1}\right)$ on the curve.
10. Diameters. A diameter has already been defined (Art. 129) as the locus of the middle points of a system of parallel chords, and in Art. 152 the equation was derived for a diameter of an ellipse. By the same method, if a system of parallel chords of the hyperbola

$$
\frac{x^{2}}{a^{2}}-\frac{y^{2}}{b^{2}}=1
$$

have the common slope $m$, the equation of the corresponding diameter will be found to be

$$
\begin{equation*}
y=\frac{b^{2}}{a^{2} m} x \tag{71}
\end{equation*}
$$

This equation shows that every diameter of the hyperbola passes through the center.

Conversely, it is true, as in the case of the ellipse, that every chord of the hyperbola through the center is a diameter. That chord of the original set which passes through the center is the diameter conjugate to [71]; and its equation is

$$
y=m x . \quad . \quad . \quad . \quad[72]
$$

Letting $m^{\prime}$ be the slope of a dimmeter, and $m$ that of its conjugate, the onsential condition that two diameters should be conjugate to each other is that (ef. Art. 158)

$$
\begin{equation*}
m m^{\prime}=\frac{8^{2}}{a^{2}} \tag{78}
\end{equation*}
$$

172. Properties of conjugate diameters of the hyperbola.
(a) It is clear that the condition

$$
\begin{equation*}
m m^{\prime}=\frac{b^{2}}{a^{2}} \quad . \quad . \tag{78}
\end{equation*}
$$

bulds also for the hypermola

$$
\frac{x^{2}}{-a^{2}}+\frac{y^{2}}{b^{3}}=1
$$

which is conjugate to the given hyperbola; for, replacing $a^{2}$ by $-a^{2}$ and $-b^{2}$ by $b^{2}$ leaves equation [73] unchanged. Hence, diameters which are conjugate to each other for a given hyperbola are conjugates also for the conjugate of that hyperbola.
( $\beta$ ) The axes of the hyperbola are clearly diameters of the curve. They are perpendicular to each other, and therefore satisfy the relation

$$
m m^{\prime}=-1
$$

Comparing this condition with that of equation [73], it follows that the transverse and conjugate axes of the hyperfinla are the only pair of perpendicular conjugate diameters (cf. ( $\beta$ ) p. 255).

If $a=b$, the condition [78] reduces to

$$
m m^{\prime}=1 ;
$$

therefore (Art. 16), in the rectangular hyperbola the sum of the angles which a pair of conjugate diameters make with the transverse axis is $90^{\circ}$ (cf. Art. 156).
$(\gamma)$ Since in equation [73] the proluct $\mathrm{mm}^{\prime}$ is positive, it follows that the angles which conjugate diameters make with the transverse axis are both acute, or both obtuse. Moreover,

$$
\text { if } m< \pm \frac{b}{a} \text {, then } m^{\prime}> \pm \frac{b}{a}
$$

and the diameters lie on opposite sides of an asymptote. Two conjujate diameters lie in the same quadrant formed by the axes of the hyperbola, on opposite sides of the asymptote (cf. Art. 155 (a)).
( $\delta$ ) An asymptote passes through the center of an hyperbola, hence may be regarded as a diameter. Its slope is

$$
m= \pm \frac{b}{a}, \quad \therefore m^{\prime}= \pm \frac{b}{a}
$$

hence, an asymptote regarded as a diameter is its ou'n conjugate; it may be called a self-conjugate diameter.

This is a limiting case of $(\boldsymbol{\gamma})$ above.
( $\epsilon$ ) It follows from this last fact that if a diameter intersects a given hyperbola, then the conjugate diameter does not intersect it, but cuts the conjugate hyperbola. It is customary and useful to define as the extremities of the conjugate diameter its points of intersection with the conjugate hyperbola. With this limitation, it follows from (a) of this article, that, as in the ellipse, each of two conjugate diameters bisects the chords parallel to the other.
$(\zeta)$ As a limiting case of this last proposition, also, it is evident that the tangent at the end of a diameter is parallel to the conjugate diameter.

By reasoning entirely analogous to that given in Art. 1555, for the ellipse, properties similar to those there given may be derived for the hyperbola. They are included in the following exercises, to be worked out by the student.

## EXERCISES

1. Find the equation of the dianueter of the hypertuols

$$
9 x^{2}-16 y^{4}=25
$$

whith bisects the chords $y=3 x+4$.
Find aleo the conjugate diameter.
2. Find, for the lygperbola of Ex. 1, a diameter through the point (1, 1), and its conjugate.
3. Find the diameter of the hyperbola $\frac{x^{2}}{10}-\frac{y^{3}}{25}=1$ which is cons jugate to the dimmeter $x-3 y=0$.
4. Find the equation of a chord of the loypmorkola $12 x^{2}-8 y^{3}=105$. which is bisected at the point $(1,2)$.
5. Lines from any pwint of an equilateral hypertwila to the extremities of a diameter make equal angles with the asymptotes.
6. Show that, in an equilateral hyperbola, conjugate diametens make equal angles with the asymptotes.
7. The difference of the squares of two conjugate semi-liameters is comstant; it is equal to the difference of the squares of the smimiaxes.
8. The angle between two conjugate diameters is sin $-\frac{10 b}{q b}$.
9. The polar of one end of a diameter of an hyperbola, with reference to the conjugate hyperbola, is the tangent at the other end of the given diameter.
10. Tangents at the ends of a pair of conjugate diameters intensect on an aymuptote.
173. Supplemental chords. As previously defined, chords of a curve are supplemental when drawn from any point of the curve to the extremities of a diameter. If, in the amalytie work of Art. 155, $b^{2}$ is replaceed by $-h^{2}$, then, if $m$ and $m$ ' are the slopes of two supplemental chords of the hyperbola, they must satisfy the relation

$$
\begin{equation*}
m m^{\prime}=\frac{b}{a^{2}} . \tag{1}
\end{equation*}
$$

But this is (see Eq. [73]) the condition that exists between the slopes of two conjugate diameters. Therefore, supplemental cherds are parrallel to a pair ef conjugate diumeters.

For the equilateral hypertmola, i.e, when $a=s$, this relation has the special value

$$
\begin{equation*}
m n^{\prime}=1 \tag{2}
\end{equation*}
$$

and, therefore, the sum of the acute angles which a pair of supplementary chords of the equilateral hyperbola make with its transverse axis is $00^{\circ}$ (cf. Art. 172 ( $\beta$ )).
174. Equations representing an hyperbola, but involving only one variable.
(a) Eccentric angle. In the theory of the hyperbola, the auxiliary circles described upon the axes of the curve as diameters are not as useful as the corresponding circles for the ellipse, since the ordinate for a point on the hyperbola does not cut the $x$-auxiliary circle, and, therefore, there is no simple construction for the eccentric angle. It is, however, sometimes desirable to express by means of a single variable the condition that a point shall be on au hyperbola; and for this purpose the equations

$$
\begin{equation*}
x=a \sec \phi, y=b \tan \phi, \tag{74}
\end{equation*}
$$

similar to equations [60], may be used; for these evidently satisfy the equation of the hyperbola

$$
\begin{aligned}
\frac{x^{2}}{a^{2}}-\frac{y^{2}}{b^{2}} & =1 \\
\sec ^{2} \phi-\tan ^{2} \phi & =1
\end{aligned}
$$

since
The angle $\phi$ may be defined as the eccentric angle for the hyperbola, and the corresponding point of the curve may be constructed as follows:

Draw the auxiliary circles, and any $\angle A O Q=\phi$. At the points $R$ and $Q$, where the terminal side of $\phi$ cuts the circles, draw tangents cutting the transverse axis in the points $M^{\prime}$ and $M$, respectively. Erect at $M$ an
 For, in the night triaugle UMQ.

$$
O M \operatorname{con} \phi=U Q, \quad \text { iec, } O M=\operatorname{asec} \phi ;
$$

and, in the right triangle $O M I^{\prime} N$,

$$
M R=O R \tan \phi, \quad \text { i.e. } M R=b \operatorname{con} \phi
$$

Hat for the point $P$.

$$
\begin{aligned}
& x=O M, y=M P=M \prime \boldsymbol{R} ; \\
& \text { bence } \quad \\
& z=a \sec \phi y=b \tan \phi .
\end{aligned}
$$

and $P$ is a point on the hyperlmola.*
The ecosentrie angle for any given point, $P$, of an hyperbola is eavily chisined. Draw the ordinate MP', and from its foop, M, draw a tangroit $\mathbb{A} Q$ to the ransiliary circle; then the angle $M O Q$ is the ecomentie angle corresponding to $P$.
( $\beta$ ) The equation of the hyperbola referred to its asymptotes, viz $x y=c^{2}$, is satisfied by the courdinates $x=c t, y=c$, whatever the values of $t$. The use of this single independent variable $t$ is sometimes convenient in dealing with points on the hyperthola.*

## EXAMPLES ON CHAPTER XI

1. Write the equation of an hyperbola whose transverse axis is $\mathbb{S}_{0}$ and the conjugate axis one half the distance bet ween the foci.
2. Find the equation of that diameter of the hyperbola $16 r^{2}-9 \eta^{2}=114$ which passes through the point ( $5, \frac{19}{3}$ ); alno find the courdinates of the extremities of the conjugate diameter.
3. Assume the equation of the hyperbola, and show that the difference of the focal distances is constant.
4. Find the locus of the vertex of a triangle of given base $2 c$, if the difference of the two other sides is a constant, and equal to 2 a .
5. Find the locus of the vertex of a triangle of given lase, if the difference of the tangents of the base angles is constant.
6. Find an expression for the angle between any pair of eonjugate diameters of as hyperbole.
7. Show that two eoneentric rectangular hyperlmolas whose axes meet at an angle of $45^{\circ}$. cut each other orthogonally.
[^40][^41]8. The portions of any chord of an hyperbola intercepted between the curve and its conjugate are equal.

Sugarstios. Draw a tangent parallel to the line in question.
9. The coordinates of a print are $a \tan (\theta+a)$ and $b \tan (\theta+\beta)$; prove that the locus of the point, as $\theta$ varies, is an hyperbola.
10. Prove that the asymptotes of the hyperbola $x y=3 x+5 y$ are $x=5$ and $y=8$.
11. If the coordinate axes are inclined at an angle $\omega$, find the equation of an hyperbola whose asymptotes are the lines $x=2$ and $y=-3$, respectively, and which passes through the point $(2,1)$.
12. Find the coördinates of the points of contact of the common tangents to the hyperbolas,

$$
x^{2}-y^{2}=3 a^{2}, \text { and } x y=2 a^{2}
$$

13. If a right-angled triangle be inscribed in a rectangular hyperbola, prove that the tangent at the right angle is perpendicular to the hypothenuse.
14. Show that the line $y=m x+2 k \cdot \sqrt{-m}$ always touches the hyperbola $x y=k^{-2}$; and that its point of contact is $\left(\frac{k}{\sqrt{-m}}, k \cdot \sqrt{-m}\right)$.
15. Find the point of the rectangular hyperbola $x y=12$ for which the subtangent is 4 . Find the subnormal for the same point.
16. Find the polar of the point $(5,3)$ on the hyperbola $x^{2}-2 y^{2}=7$, with respect to the conjugate hyperbola. Show that this line is tangent to the given hyperbola, at the other end of the diameter from $(5,3)$.
17. If an ellipse and hyperbola have the same foci, they intersect at right angles.
18. Find tangents to the hyperbola $2 y^{2}-16 x^{2}=1$ which are perpendicular to its asymptotes.
19. Find normals to the hyperbola $\frac{(x-3)^{2}}{16}-\frac{(y-2)^{2}}{9}=1$ which are parallel to its asymptotes. Find the polar of their point of intersection.
20. Show that, in an equilateral hyperbola, conjugate diameters are equally inclined to the asymptotes.
21. Show that two conjugate diameters of a rectangular hyperbola are equal.
22. Show that, in an equilateral hyperlwila, Iwo diametern at richet angles to each other are equal. Show also that this follow from R.s. 21.
23. I variable circle is always tangent to each of two fixed circles; pruse that the locus of its center is either an hyperbola or an ellipes.
24. Find the common tangents to tho hyperbola $\frac{z^{0}}{a^{3}}-\frac{y^{3}}{b^{3}}=1$ and its mid-circle $x^{2}+y^{8}=$ ab.
25. In the hypertwia $25 x^{2}-16 y^{2}=100$, find the conjugate diametern that eut each uther at ant angle of $43^{\circ}$.
26. The latus rectum of an hyperbola is a third proportional to tho two axes.
27. The polans of any proint $(h, k)$ with respect to conjugate hypertwolan arv parallel.
28. The sum of the eccentric angles of the extremities of twe conjugrate diameters of an lyyperbola is equal to $900^{\circ}$; i.e., $\phi+\phi^{\prime \prime}$ an $90^{\circ}$.
29. Find the equation of a line through the focus of an hygerbola and the focus of its conjugate, and find the prole of that line.
30. Find the asymptotes of the hyperbola $x y-3 x-2 y=0$. What is the equation of the conjugate hypertiola?
31. Show that the $y$-axis is an asymptote of the hyperbola

$$
2 x y+3 x^{2}+4 x=9 .
$$

What is the equation of the other asymptote? Of the conjugate hyperbola?
32. If two tangents are drawn from an external point to an hyperbola, they will touch the same or opposite branches of the curve according as the given proint lies between or outside of the asymptotes.

## CHAPTER XII

## GENERAL EQUATION OF THE SECOND DEGREE

$$
A x^{2}+2 \boldsymbol{H} x y+B y^{2}+2 \boldsymbol{G} x+2 \boldsymbol{F} y+C=0
$$

175. General equation of the second degree in two variables. Thus far only special equations of the second degree have been studied; they have all been of the form

$$
\begin{equation*}
A x^{2}+B y^{2}+2 G x+2 F y+C=0 \tag{1}
\end{equation*}
$$

i.e., they have been free from the term containing the product of the variables. In Arts. 107, 113, and 119 it is shown that equation (1) represents a conic section having its axes parallel to the coördinate axes. It still remains to be shown, however, that the most general equation of the second degree, viz.

$$
\begin{equation*}
A x^{2}+2 H x y+B y^{2}+2 G x+2 F y+C=0, \tag{2}
\end{equation*}
$$

also represents a conic section. To prove this it is only necessary to show that, by a suitable change of the coördinate axes, equation (2) may be reduced to the form of equation (1).

If equation (2) be referred to new axes, $O X^{\prime}$ and $O Y^{\prime}$, say, making an angle $\theta$ with the corresponding given axes; and if the new coördinates of any point on the curve be $x^{\prime}$ and $y^{\prime}$, the old coördinates of the same point being $x$ and $y$; then (Art. 72)

$$
\begin{equation*}
x=x^{\prime} \cos \theta-y^{\prime} \cdot \sin \theta, \text { and } y=x^{\prime} \sin \theta+y^{\prime} \cos \theta . . \tag{3}
\end{equation*}
$$

Substituting theme values (3) in equation (2), it becornes

$$
A\left(x^{\prime} \cos \theta-y^{\prime} \sin \theta\right)^{3}+2 \Pi\left(x^{\prime} \cos \theta-y^{\prime} \sin \theta\right)\left(x^{\prime} \sin \theta+y^{\prime} \cos \theta\right)
$$

$$
\begin{align*}
& +B\left(x^{\prime} \sin \theta+y^{\prime} \cos \theta\right)^{2}+2\left(\vec{F}\left(x^{\prime} \cos \theta-y^{\prime} \sin \theta\right)\right. \\
& +2 \boldsymbol{F}^{\prime}\left(x^{\prime} \sin \theta+y^{\prime} \cos \theta\right)+G=0, \tag{4}
\end{align*}
$$

which, being expanded and re-arranged, beoomes :
$x^{\prime 2}\left(A \cos ^{2} \theta+2 H \sin \theta \cos \theta+B \sin ^{2} \theta\right)$
$+x^{\prime} y^{\prime}\left(-2 A \sin \theta \cos \theta-2 I \sin ^{2} \theta+2 \Pi \cos ^{2} \theta+2 B \sin \theta \cos \theta\right)$
$+y^{\prime 2}\left(A \sin ^{2} \theta-2 \Pi \sin \theta \cos \theta+B \cos ^{2} \theta\right)$
$+2^{2}(2(2 \cos \theta+2 F \sin \theta)$
$+y^{\prime}(-2 G \sin \theta+2 F \cos \theta)+C=0$. . . . (5)
This transformed equation ( 5 ) will be free from the term containing the product $x^{\prime} y^{\prime}$ if $\theta$ be so chosen that
$-2 A \sin \theta \cos \theta-2 H \sin ^{2} \theta+2 H \cos ^{2} \theta+2 B \sin \theta \cos \theta=0$,
i.e., if $\quad 2 H\left(\cos ^{2} \theta-\sin ^{2} \theta\right)=(A-B) 2 \sin \theta \cos \theta$,
i.e., if $\quad 2 H \cdot \cos 2 \theta=(A-B) \sin 2 \theta$,
or finally, if

$$
\begin{equation*}
\tan 2 \theta=\frac{2 H}{A-B} \tag{6}
\end{equation*}
$$

Moreover, it is always possible to choose a positive acute angle $\theta$ so as to satisfy this last equation whatever may be the numbers represented by $A, B$, and $I$.

Having chosen $\theta$ so as to satisfy equation (6), and having suhstituted the values of $\sin \theta$ and $\cos \theta$ in equation (5), that equation reduces to

$$
\begin{equation*}
A^{\prime} x^{\prime 2}+B^{\prime} y^{\prime 2}+2 G^{\prime} x^{\prime}+2 F^{\prime \prime} y^{\prime}+C=0, \tag{7}
\end{equation*}
$$

(wherein $A^{\prime}, B^{\prime}, \cdots$ represent the new coefficients)
and therefore represents a conic section with its axes parallel to the new ooordinate axes. But equation (i) represents
the same locus as equation (2); hence it is proved that, in rectangular coördinates, every equation of the form

$$
A x^{2}+2 H x y+B y^{2}+2 G x+2 F y+C=0
$$

represents a conic section whose axes are inclined at an angle $\theta$ to the given coorrdinate axes, where $\theta$ is determined by the equation

$$
\tan 2 \theta=\frac{2 H}{A-B}
$$

It is to be noted that the constant term $C$ has remained unchanged by the transformation given above.

The next article will illustrate the application of this method to numerical equations. It is to be observed that this method is entirely general, and enables one to fully determine the conic represented by any given numerical equation of the second degree.

Note. In the proof just given that every equation of the second degree represents a conic section, it is assumed that the given axes are at right angles. This restriction may, however, be removed; for if they are not at right angles, a transformation may be made to rectangular axes having the same origin (ef. Arts. 74, 75), and the equation will have its form and degree left unchanged; after which the proof already given applies.
176. Illustrative examples. Example 1. Given the equation

$$
\begin{equation*}
-x^{2}+4 x y-y^{2}-4 \sqrt{2} x+2 \sqrt{2} y-11=0 \tag{1}
\end{equation*}
$$

to determine the nature and position of its locus.
Turn the axes through an angle $\theta$, i.e., substitute for $x$ and $y$, respectively, $x^{\prime} \cos \theta-y^{\prime} \sin \theta$ and $x^{\prime} \sin \theta+y^{\prime} \cos \theta$; equation (1) then becomes

$$
\begin{align*}
x^{\prime 2}\left(-\cos ^{2} \theta\right. & \left.+4 \sin \theta \cos \theta-\sin ^{2} \theta\right) \\
& +x^{\prime} y^{\prime}\left(+2 \sin \theta \cos \theta+4 \cos ^{2} \theta-4 \sin ^{2} \theta-2 \sin \theta \cos \theta\right) \\
& -y^{2}\left(\sin ^{2} \theta+4 \sin \theta \cos \theta+\cos ^{2} \theta\right) \\
& -x^{\prime}(4 \sqrt{2} \cos \theta-2 \sqrt{2} \sin \theta) \\
& +y^{\prime}(+4 \sqrt{2} \sin \theta+2 \sqrt{2} \cos \theta)-11=0 . \quad . \quad . \tag{2}
\end{align*}
$$

The coerficient of $z^{\prime} y^{\prime}$ in equation $(2)$ reduces to $4\left(\sin ^{2} \theta-\cos ^{2} \theta\right)$; it will therefore be zero if $\sin \theta=\cos \theta$, i.e., if $\theta=45^{\circ} \cdot$

If $\theta=45^{\circ}$, then $\sin \theta=\cos \theta=\frac{1}{\sqrt{2}}$, and this value of $\sin \theta$ and $\cos \theta$ being substituted in ofyuation (2), it tecomes

$$
\begin{equation*}
z^{2}-3 y^{2}-2 x^{2}+6 y^{\prime}-11=0 \tag{3}
\end{equation*}
$$

which represents the same locus as is representeed by equation (1); the difference in the form of the two equations leeing due te the fact that the axes to which equation (3) is referreal make an angle of $45^{\circ}$ with the axes to which equation (1) is referred.

Enguation (3) may be writhen in the form
1.8.,

$$
\begin{align*}
& \left(x^{2}-1\right)^{2}-3\left(y^{\prime}-1\right)^{2}=0, \\
& \frac{\left(x^{2}-1\right)^{2}}{3^{2}}-\frac{\left(y^{2}-1\right)^{2}}{(\sqrt{3})^{2}}=1, \tag{4}
\end{align*}
$$

which represents an hyperhola (cf. Art. 118). Its center is at the point ( 1,1 ) : the transverse axis is parallel wo the $z^{\prime}$-axis; the semi-ases are of length is and $\sqrt{3}$, respeotively; the ecoentricity is $e=1 \sqrt{3}$; the foci are at the points $F \equiv(1+2 \vee \overline{3}, 1)$ and $F \equiv(1-2 \sqrt{3}, 1)$, respectively; the directrices have the equations

$$
x^{\prime}=1+1 \sqrt{3}
$$

and $x^{\prime}=1-1 \sqrt{3}$,
respectively; and the latus rectum is 2 . All these results refer to the new axes, of course, and the tocus is that represented in Fig. 121.

Tra. 1 an.

- This accords with a result of the precerling article, viz. that to tree an equation from ita ry-term it is only necesomary to turn the axes flrmugh a prasitive acute angle determined by $\tan 2 \theta=\frac{311}{A-B}$. In the present pmblem $U=+2$ and $A=B=-1$, hence $\tan 2 \theta=x \operatorname{and} \theta=45^{\circ}$.

Example 2. Given the equation

$$
\begin{equation*}
4 x^{2}+4 x y+y^{2}-18 x+26 y+84=0 \tag{5}
\end{equation*}
$$

to determme the nature and position of its locus. Turn the axes through an angle $\theta$, i.e., substitute for $x$ and $y$, respectively, $x^{\prime} \cos \theta-y^{\prime} \sin \theta$ and $x^{\prime} \sin \theta+y^{\prime} \cos \theta$; equation (5) then becomes

$$
\begin{align*}
x^{\prime 2}\left(4 \cos ^{2} \theta\right. & \left.+\sin ^{2} \theta+4 \sin \theta \cos \theta\right) \\
& +x^{\prime} y^{\prime}\left(-8 \cos \theta \sin \theta+2 \cos \theta \sin \theta-4 \sin ^{2} \theta+4 \cos ^{2} \theta\right) \\
& +y^{\prime 2}\left(4 \sin ^{2} \theta+\cos ^{2} \theta-4 \sin \theta \cos \theta\right) \\
& +x^{\prime}(-18 \cos \theta+26 \sin \theta) \\
& +y^{\prime}(18 \sin \theta+26 \cos \theta)+64=0 \tag{6}
\end{align*}
$$

in which $\theta$ is to be so determined that the coefficient of $x^{\prime} y^{\prime}$ shall be zero. On placing this coefficient equal to zero, it is at once seen that tan $2 \theta=\frac{4}{3}$, from which it follows (cf. exercise 3, Art. 16, second method) that

$$
\sin 2 \theta=\frac{8}{8} \text { and } \cos 2 \theta=8 ;
$$

remembering that $\cos 2 \theta=\cos ^{2} \theta-\sin ^{2} \theta=2 \cos ^{2} \theta-1=1-2 \sin ^{2}$ it is easily deduced that $\sin \theta=\frac{1}{\sqrt{5}}$ and $\cos \theta=\frac{2}{\sqrt{5}}$

Substituting these values in equation (6), it becomes
.e,

$$
\begin{align*}
& 5 x^{\prime 2}-2 \sqrt{5} x^{\prime}+14 \sqrt{5} y^{\prime}+64=0 \\
& \left(x^{\prime}-\frac{1}{\sqrt{5}}\right)^{2}=-\frac{14}{\sqrt{5}}\left(y^{\prime}+\frac{63}{14 \sqrt{5}}\right) ; \tag{7}
\end{align*}
$$

which is the equation of a parabola whose vertex is at the point

$$
\left(\frac{1}{\sqrt{5}},-\frac{63}{14 \sqrt{5}}\right)
$$

whose focus is at the point $\left(\frac{1}{\sqrt{5}},-\frac{8}{\sqrt{5}}\right)$, whose axis is parallel to the negative end of the $y$ 'axis, and whose latus rectum is $\frac{14}{\sqrt{5}}$. All these results refer to the new axes; the locus of the above equation is given in Fig. 79, p. 178 (Art. 108).

## EXERCISES

1. For the hyperbola in Fig. 121 find the coördinates of the center and of the foci, and also the equations of its axes and directrices, all referred to the axes $O X$ and $O Y$.

By first removing the ay-term, determine the wature inud pmontion of the toci represented by the following equatiotis. Also phat the curves.
2. $x^{3}-2 \sqrt{3} x y+3 y^{2}-24 x-8 \sqrt{3} y+10 \sqrt{3}=0$.
3. $x^{2}-4 \sqrt{ } 3 x y+2 y^{2}+\sqrt{5} x+10 y=0$.
4. $3 x^{8}+2 x y+3 y^{3}-16 y+23=0$.
5. $x^{2}-2 x y+y^{3}-0 x-6 y+0=0$.
177. Test for the species of a conic. It is often desirable to know the species of a conio represented by a given equation even when it may not be necessary to sletermine fully the position of the curve. Remembering that every equation of the second degree represents a conie (Art. 175), and also that the three species of conies may tre distinguished from each other by the number of directions in which lines meeting the curve at infinity may be drawn through any given point (Art. 131, Note), it is easy to find a test that will enable one to distinguish at a glance the kind of conic represented by a given equation.

Let the given equation be

$$
\begin{equation*}
A x^{2}+2 H x y+B y^{2}+2 G x+2 F y+G=0 . \tag{1}
\end{equation*}
$$

If this equation be transformed to polar coobrdinates, the origin bring the pole and the $x$-axis the initial line, so that $x=p \cos \theta$ and $y=\rho \sin \theta$, it beoomes

$$
\begin{align*}
\rho^{2}\left(A \cos ^{2} \theta\right. & \left.+2 H \sin \theta \cos \theta+B \sin ^{2} \theta\right) \\
& +2 \rho(G \cos \theta+F \sin \theta)+C=0 . \tag{2}
\end{align*}
$$

One value of $\rho$, determined by this equation, will be infinite if its direction be such that

$$
A \cos ^{2} \theta+2 H \sin \theta \cos \theta+B \sin ^{2} \theta=0 ; \quad[\text { Art. 10] }
$$

i.e., if

$$
B \tan ^{2} \theta+2 H \tan \theta+A=0
$$

i.e., if

$$
\begin{equation*}
\tan \theta=\frac{-H_{ \pm} \sqrt{H^{2}-A B}}{B} \tag{8}
\end{equation*}
$$

Equation (3) shows that $\tan \theta$ will have
two imaginary values, if

$$
H^{2}-A B<0
$$

two real and coincident values, if $H^{2}-A B=0$;
two real and distinct values, if $\quad H^{2}-A B>0$.
Therefore, there is no direction, one direction, or there are two directions, respectively, in which a line meeting the curve in an infinitely distant point may be drawn through the origin, according as

$$
H^{2}-A B \text { is }<0,=0, \text { or }>0 ;
$$

and hence,
if $H^{2}-A B<0$, equation (1) represents an ellipse,
if $H^{2}-A B=0$, equation (1) represents a parabola,
if $H^{2}-A B>0$, equation (1) represents an hyperbola.
178. Center of a conic section. As already defined (Arts. $111,117,120$ ), the center of a curve is a point such that all chords of the curve passing through it are bisected by it. It has also been shown that such a point exists for the ellipse and hyperbola, i.e., that these are central conics.

If the equation of the conic is given in the form

$$
\begin{equation*}
A x^{2}+2 H x y+B y^{2}+2 G x+2 F y+C=0 \tag{1}
\end{equation*}
$$

the necessary and sufficient condition that the origin is at the center, is $G=0$ and $F=0$.

For if the origin be at the center, and $\left(x_{1}, y_{1}\right)$ be any given point on the locus of equation (1), then $\left(-x_{1},-y_{1}\right)$ must also be on this locus (because these two points are on a straight line through the origin and equidistant from it); hence the coördinates of each of these points satisfy equation (1),
i.e., $A x_{1}^{2}+2 H x_{1} y_{1}+B y_{1}^{2}+2 G x_{1}+2 F y_{1}+C=0$,
and $A\left(-x_{1}\right)^{2}+2 H\left(-x_{1}\right)\left(-y_{1}\right)$

$$
\begin{equation*}
+B\left(-y_{1}\right)^{2}+2 G\left(-x_{1}\right)+2 F\left(-y_{1}\right)+C=0 ; \tag{3}
\end{equation*}
$$

and equation (3) may be written thas:

$$
\begin{equation*}
A x_{1}^{3}+2 H x_{1} y_{1}+B y_{1}^{3}-2 G x_{1}-2 F y_{1}+G=0 \tag{4}
\end{equation*}
$$

Subtracting equation (4) from equation (2) gives

$$
\begin{align*}
4 G x_{1}+4 F y_{1} & =0 \\
G x_{1}+F y_{1} & =0 \tag{5}
\end{align*}
$$

But equation (5) is to be satisfied by the coürdinates $x_{1}$ and $y_{1}$ of every point on the locus of equation (1), and the seressary and sufficient conditions for this are

$$
G=0 \text { and } F=0 .
$$

179. Transformation of the equation of a conic to parallel axes through its center. Let the equation of the given conic be

$$
\begin{equation*}
A x^{2}+2 H x y+B y^{3}+2 G x+2 F y+C=0 \tag{1}
\end{equation*}
$$

and let the coördinates of its center be $a$ and $\beta$. Then to transform equation (1) to parallel axes through the point $(a, \beta)$ it is only necessary to substitute in that equation $x^{\prime}+\alpha$ and $y^{\prime}+\beta$ for $x$ and $y$. This substitution gives

$$
\begin{aligned}
A\left(x^{\prime}+a\right)^{2} & +2 \Pi\left(x^{\prime}+a\right)\left(y^{\prime}+\beta\right)+B\left(y^{\prime}+\beta\right)^{2} \\
& +2 G\left(x^{\prime}+a\right)+2 F\left(y^{\prime}+\beta\right)+Q=0
\end{aligned}
$$

i.e. $A x^{\prime 2}+2 I x^{\prime} y^{\prime}+B y^{\prime 2}+2 x^{\prime}(A a+M \beta+G)$

$$
\begin{align*}
& +2 y^{\prime}(H a+B \beta+F)+A a^{2}+2 H a \beta+B \beta^{2} \\
& +2 G a+2 F \beta+C^{\bullet}=0 . \tag{2}
\end{align*}
$$

Since $a$ and $\beta$ are the coördinates of the center (Art. 178),

$$
\begin{equation*}
A a+H \beta+G=0 \text { and } \Pi a+B \beta+F=0 ; \tag{3}
\end{equation*}
$$

[^42]solving these equations gives
\[

$$
\begin{equation*}
a=\frac{B G-F H}{H^{2}-A B} \quad \text { and } \quad \beta=\frac{A F-G H}{H^{2}-A B} \tag{4}
\end{equation*}
$$

\]

which are the coördinates of the center of the locus of equation (1).

The constant term in equation (2) is,

$$
A a^{2}+2 H a \beta+B \beta^{2}+2 G a+2 F \beta+C,
$$

$$
=a(A a+H \beta+G)+\beta(H a+B \beta+F)+G a+F \beta+C
$$

$$
\begin{equation*}
=G a+F \beta+C, \quad[\text { by virtue of equations (3) }] . \tag{5}
\end{equation*}
$$

$=G\left(\frac{B G-F H}{H^{2}-A B}\right)+F\left(\frac{A F-G H}{H^{2}-A B}\right)+C, \quad[$ by equation (4) $]$
$=-\frac{A B C+2 F G H-A F^{2}-B G^{2}-C I^{2}}{H^{2}-A B}=-\frac{\Delta}{H^{2}-A B}$,
wherein

$$
\Delta \equiv A B C+2 F G H-A F^{2}-B G^{2}-C H^{2}(\text { ef. Art. } 67)
$$

Equations (4) show that the center of the locus of equation (1) is a definite point, at a finite distance from the origin, if $H^{2}-A B \neq 0$, but that the coördinates of this center become infinite if $H^{2}-A B=0$. Hence (cf. Art. 177), while the ellipse and hyperbola each have a definite finite center, the parabola may be regarded as having a center at infinity.

By making use of equations (3) and (5), equation (2) may be written

$$
\begin{equation*}
A x^{\prime 2}+2 H x^{\prime} y^{\prime}+B y^{\prime 2}-\frac{\Delta}{H^{2}-A B}=0 \tag{6}
\end{equation*}
$$

hence, if the general equation of an ellipse or hyperbola be transformed to parallel axes through the center of the conic. the coefficients of the quadratic terms remain unchanged,
those of the first degree terms vanish, and the new ahasinte term becomes

$$
-\frac{\Delta}{I^{2}-A B}
$$

Nots. Two special eases should te noted

1) Equation (5) shows that if $\Delta=0$, the loens of equation (1) con siate of twa straight lines through the new origin (el. Art, हf).
2) The priet ( $a, \beta$ ) is the intersection of the two atraight lines

$$
A s+H y+G=0 \text { and } H x+B y+F=0 . \quad \text { (c. eq. (B) above.) }
$$

If $\frac{A}{I I}=\frac{I I}{13}=\frac{G}{f}$, then these lines are coincident (Art. 3s, (j) ), and the motrifinates a and $\beta$ become indeterminate. In this case, it may be shown that $\Delta=0$; that the loevs of equation (1) conabsts of two times prarallet to, on oppusite sides of, and equidistant from, the lin $A x+11 y+G=0$; hence any point of the latter lime may le considered as a center, since chords drawn through such a point are lisected hy it, i.e., the curre has a line of centers. Again, since $H^{2}-A B=0$, this locus may be considered a special form of a paratoola.
180. The invariants $A+B$ and $I F-A B$. In Art. 175 it was shown that a transformation of coordinates by rotating the axes through an angle $\theta$ changes the coefficients of the equation

$$
\begin{equation*}
A x^{2}+2 \Pi x y+B y^{2}+2 G x+2 F y+c^{y}=0 \tag{1}
\end{equation*}
$$

with the exception of the constant term. It is true, however, that certain functions of these conflicients are not changed by this transformation, e.g., the sum $A+B$ of the coeflicients of the $x^{2}$ and $y^{3}$ terms is the same after trans furmation as lefore. If the transformed equation the written

$$
\begin{equation*}
A^{\prime} x^{3}+2 H^{\prime} x y+B^{\prime} y^{2}+2 G^{\prime} x+2 F^{\prime} y+C^{\prime}=0 . \tag{2}
\end{equation*}
$$

wherein, as in Art. 175,

$$
\begin{align*}
A^{\prime} & =A \cos ^{2} \theta+2 \Pi \sin \theta \cos \theta+B \sin ^{2} \theta  \tag{3}\\
B^{\prime} & =A \sin ^{2} \theta-2 \Pi \sin \theta \cos \theta+B \cos ^{2} \theta  \tag{4}\\
\text { and } \quad 2 H^{\prime} & =2 H \cos 2 \theta-(A-B) \sin 2 \theta_{1} \tag{5}
\end{align*}
$$

then the addition of equations (3) and (4)
gives $\quad \boldsymbol{A}^{\prime}+\boldsymbol{B}^{\prime}=\boldsymbol{A}+\boldsymbol{B}\left(\right.$ since $\left.\sin ^{2} \theta+\cos ^{2} \theta=1\right)$.
Again, $\quad A^{\prime}-B^{\prime}=2 H \sin 2 \theta+(A-B) \cos 2 \theta$.
hence

$$
\begin{align*}
\left(A^{\prime}-B^{\prime}\right)^{2}+4 H^{\prime 2} & =\left\{(A-B)^{2}+4 H^{2}\right\}\left(\sin ^{2} 20+\cos ^{2} 2 \theta\right),  \tag{7}\\
& =(A-B)^{2}+4 H^{2}, \quad . \quad . \quad(8) \tag{8}
\end{align*}
$$

i.e., $A^{\prime 2}-2 A B^{\prime}+B^{\prime 2}+4 H^{\prime 2}=A^{2}-2 A B+B^{2}+4 H^{2}$.

But by (6),

$$
A^{\prime 2}+2 A^{\prime} B^{\prime}+B^{\prime 2}=A^{2}+2 A B+B^{2}
$$

hence, by subtraction,

$$
\begin{equation*}
H^{2}-A B=H^{2}-A B, \tag{9}
\end{equation*}
$$

and the function $H^{2}-A B$ is also unchanged by the transformation of coördinates, through the angle $\theta$. Moreover, if a transformation of courdinates to a new origin be performed as in Art. 179, $A, B$, and $H$ are not changed, nor, therefore, the functions $A+B$ and $H^{2}-A B$. Such functions of the coefficients, which do not vary when the transformations of Arts. 175 and 179 are performed, are called invariants of the equation for those transformations.

If, as in Art. 175, $\theta$ be chosen so that

$$
\begin{equation*}
\tan 2 \theta=\frac{2 H}{A-B}, \tag{10}
\end{equation*}
$$

then $H^{\prime}=0$, and equation (9) becomes

$$
\begin{equation*}
-A^{\prime} B^{\prime}=H^{2}-A B \tag{11}
\end{equation*}
$$

Again, from eq. (10), $\sin 2 \theta=\frac{2 H}{\sqrt{(A-B)^{2}+4 H^{2}}}$,
and

$$
\begin{equation*}
\cos 2 \theta=\frac{A-B}{\sqrt{(A-B)^{2}+4 H^{2}}} ; \tag{12}
\end{equation*}
$$

hence, equation (8), $A^{\prime}-B^{\prime}=\frac{2 H}{\sin 2 \theta}$.
Since $\sin 2 \theta$ is positive (Art. 175), therefore the sign of $A^{\prime}-B^{\prime \prime}$ is the same as the sign of $\boldsymbol{I}$.

These results are useful in reslucing an equation of a conte to its simplest standard form, as will tee illastrated in the following artiole.
181. To reduce to its simplest standard form the general equation of a conic. a. Ceneral conic. The renult of Art. 1 so euabiles whe to swhere to its sicplest form a given equation of the megomel dogree, in
 If the equation of the conic,

$$
\begin{equation*}
A x^{2}+2 I I_{x y}+B y^{2}+2 G s+2 F g+C=0, \tag{1}
\end{equation*}
$$

the first transformed to the center of the curve ns origin, the reaulting equation becomes (Art. 179)

$$
\begin{equation*}
A x^{3}+2 H x y+B y^{2}+C=0 . \tag{2}
\end{equation*}
$$

If equation (2) be now transformed to axes $\sigma X^{-}$and $(\sigma)^{m}$, making tho angle $\theta$ with $O X^{3}$ and or 8 , respectively, such that

$$
\tan 2 \theta=\frac{2 \pi}{A-B},
$$

It will become (Art. 175) $A^{2} z^{2}+B y^{2}+C=0$, (3) wherein the new coeff. cionts are easily determined by the relations

$$
\begin{aligned}
& C^{\prime}=G a+F \beta+C \\
&=-\frac{\Delta}{H^{2}-A B} \\
&(A r t .170), \\
& A^{\prime}+B^{\prime}=A+B, \\
& \text { and }-A B^{\prime}=H^{2}-A B
\end{aligned}
$$

(Art. 180).
Kixauple. Suppose the given equation to be

$$
\begin{equation*}
8 x^{4}+2 x y+3 y^{3}-18 y+20=0, \tag{4}
\end{equation*}
$$

in which $A=3, H=1, B=3, G=0, F=-8$, and $C=20$.
Then $H^{3}-A B=-8$, and the locus is an ellipes.

The coordinates of the center are $\alpha=-1, \beta=3$.
Therefore, $\quad C^{\prime}=G a+F \beta+C=-4 ; \quad A^{\prime}+B^{\prime}=6,-A^{\prime} B^{\prime}=-8$;
and, since $A^{\prime}$ is larger than $B^{\prime}, H$ being positive (Art. 180),
hence

$$
A^{\prime}=4, B^{\prime}=2 ;
$$

while $\tan 2 \theta=\infty$, and therefore $\theta=45^{\circ}$. The transformed equation is therefore
i.e.,

$$
\begin{gather*}
4 x^{2}+2 y^{2}-4=0, \\
\frac{x^{2}}{1}+\frac{y^{2}}{2}=1, \tag{5}
\end{gather*}
$$

when referred to the axes $O^{\prime} X^{\prime \prime}, O^{\prime} Y^{\prime \prime}$; and the locus is approximately as given in Fig. 122.
b. Non-central conic. If $H^{2}-A B=0$, the relations of equations (6) and (11), Art. 180, may still be used to simplify the reduction of equation (1) to the standard form for the equation of a parabola, if, as in Art. 176 , the $x y$-term be removed first. In this case, however, a better method of reduction is as follows:

Since the first three terms of equation (1) form a perfect square, that equation may be written

$$
\begin{equation*}
(\sqrt{A} x+\sqrt{B} y)^{2}+2 G x+2 F y+C=0 \tag{6}
\end{equation*}
$$

wherein the sign of the $\sqrt{B}$ is the same as that of $H$.
Equation (2) may now be transformed to new axes $O X^{\prime}$ and $O Y^{\prime}$, which are so chosen that the equation of $O X^{\prime}$ referred to the given axes shall be

$$
\sqrt{A} x+\sqrt{B} y=0
$$

hence, if $\theta$ be the angle between $O X$ and $O X^{\prime}$, then

$$
\begin{equation*}
\tan \theta=-\frac{\sqrt{A}}{\sqrt{B}} \text {, whence } \sin \theta=\frac{-\sqrt{A}}{\sqrt{A+B}} \text { and } \cos \theta=\frac{\sqrt{B}}{\sqrt{A+B}} \tag{7}
\end{equation*}
$$

Equation (7) shows that $\theta$ is negative (if the positive value of $\sqrt{A+B}$ be used), and acute or obtuse according as $\sqrt{B}$ is positive or negative. The formulas for transforming to the new axes are (cf. Art. 72)

$$
\begin{equation*}
x=\frac{\sqrt{B}}{\sqrt{A+B}} x^{\prime}+\frac{\sqrt{A}}{\sqrt{A+B}} y^{\prime} \text { and } y=\frac{-\sqrt{A}}{\sqrt{A+B}} x^{\prime}+\frac{\sqrt{B}}{\sqrt{A+B}} y^{\prime} . \tag{8}
\end{equation*}
$$

Substituting these values for $x$ and $y$ in equation (B), it becomes

$$
\begin{equation*}
(A+B) y^{\prime 2}+2 \frac{F \sqrt{B}-F \sqrt{A}}{\sqrt{A+B}} x^{\prime}+2 \frac{G \sqrt{A}+F \sqrt{B}}{\sqrt{A+B}} y^{\prime}+C=0 . \tag{9}
\end{equation*}
$$

By dividing equation (9) Ly $(A+B)$, completing the nquare of tho $g$-terms, and transpming, it may the written in the form

$$
\begin{align*}
\{y & \left.=\frac{G \sqrt{A}+F \sqrt{B}}{(A+B)^{\prime}}\right\}^{2} \\
& =-2 \frac{C \sqrt{B}-F \sqrt{A}}{(A-B)^{3}}\left\{x^{\prime}+\frac{(B \sqrt{A}+F \sqrt{B})^{2}-C(A+B)^{2}}{2(A+B)^{!}(B \sqrt{B}-F \sqrt{A})}\right\} \tag{10}
\end{align*}
$$

Comparing equation (10) with equation [12] (Ars. 105), it is semen that the length of the latus reetum, as well as the coumlinates of the sertex and focus (with reference to the axes $O X^{\circ}$ and $O Y^{\prime}$ ), and other imporcant facts, may be read directly from the equation.

The advantage of equation (10), over that resulting from the reduction of Ex. 2, Art. 176, is that, in comnection with equation (7), is gives all the facts necessary for the immediate location of the curve, and gives those facts in terms of the coeflicients of the original equation.

Examples. Iet it hee required to decermine the pusition and parameter of the parabola represented by the equation

$$
9 x^{3}-24 x y+16 y^{3}-18 x-101 y+19=0
$$

The given equation may be wrib ten as
$(3 x-4 y)^{2}-18 x-101 y+10=0$.
If the line $3 x-4 y=0$ be choeen as $x^{\prime}$ axis, then $\tan \theta=\frac{5}{6}$, whence $\sin \theta=-8$, and $\cos \theta=-\frac{f}{0}$. The formulas of transformation then are :
$x=\frac{-4 x^{2}+3 y^{\prime}}{5}$ and $y=-\frac{3 x^{2}+4 y^{\prime}}{5}$.

Sulatituting these values in equar thon (1), it becomes

$$
25 y^{\prime 2}+70 y^{\prime}=-75 x^{\prime}-10
$$

this equation may be written

$$
\left(y^{\prime}+i\right)^{2}=-8\left(x^{\prime}-i\right),
$$

which shows that the latus rectum is 3 , and the coordinates of the vertex and focus (with reference to the new axes) are, respectively, 3. $=$ is and " so - g . It also shows that the axis of the curve is garallel to the sugative end of the $r^{\prime} \cdot a x$ is.

Reealling the remark aloout the angle $\theta$ determined by equations (7) above, it is seen that the geometrie regresentation of the above eyguatiou is shoms in Fig. 122.

[^43]182. Summary. It has been shown in the preceding articles that every equation of the second degree in two variables represents a conic section, whether the axes are oblique or rectangular; and that its species and position depend upon the values of the coefficients of the equation. The various criteria of the nature of the conic represented by such an equation, in rectangular coördinates, appear in the following table:

The General Equation of the Second Degree

$$
\begin{aligned}
& A x^{2}+2 H x y+B y^{2}+2 G x+2 F y+C=0 \\
& \Delta \equiv A B C+2 F G H-A F^{2}-B G^{2}-C H^{2}
\end{aligned}
$$

I. $H^{2}-A B<0$. The ellipse.
(1) if $A=B$, and $H=0$, a circle.
(2) if $\Delta$ is + , imaginary.
(3) if $\Delta$ is - , real.
(4) if $\Delta$ is 0 , a pair of imaginary straight lines, or, a point.
II. $H^{2}-A B=0$. The parabola.
(1) if $H$ is + , axis is the new $y$-axis.
(2) if $H$ is - , axis is the new $x$-axis.
(3) if $\Delta$ is 0 , pair of parallel straight lines, which are real and different, real and coincident, or imaginary, according as $G^{2}-A C>$, $=$, or $<0$.
III. $H^{2}-A B>0$. The hyperbola.
(1) if $A=-B$, a rectangular hyperbola.
(2) if $\Delta$ is + , principal axis is the new $y$-axis.
(3) if $\Delta$ is - , principal axis is the new $x$-axis.
(4) if $\Delta$ is 0 , a pair of real intersecting straight lines.

Nurs. The ahave results have not all lesell shown, hut are mally dedueal from the work aireals given. Thus the locus of equation ( B ), Art. 151, if an ellipes, is imasimary if $\mathrm{C}^{\circ}$ is - ; but, by ajuatum ( 8 ), Art. $159, G$ is - it $\Delta$ is + ; henee the tent $1(2)$, given aloves. And so for the other tests, wheh the stedent shoula verify. The asple $\theta$ whieh the new ases make with the cull, respertively, is chosen as is Art. 175 20 being tal.en always positive and not greater than 1 sup.
183. The equation of a conic through given points. The general equation of a conic may be written

$$
\begin{equation*}
A x^{3}+2 H x y+B y^{3}+2 G x+2 F y+C=0 \tag{1}
\end{equation*}
$$

and contains five [rarameters, the five ratios between the coeflicients $A, I, B, G, F, C$. Since fire equations, or conditions, will determine those parameters, in general five pointa will determine a conic. That is, in general, a comie may be made to pass through five, and only five, given points.

If, however, the conic is to be a parabola, one equation is given ; viz. $H^{2}-A B=0$, hence only four additional conditions are needed. In general, a parabola may be made to pass through four points, only.

A circle has two comlitions given, viz. $A=B, \quad H=0$; therefore, in general, a circle may be made to pass through three pointe, only.

A pair of straight lines has one condition given, $\Delta=0$; therefore, in general, a pair of straight lines may be made to puss through four puints, only.

The method to be followed in obtaining the equation of the required conic has been used in Art. 80, and may be indicated for finding the equation of the parabola through four given points,

$$
P_{1} \equiv\left(x_{1}, y_{1}\right), P_{2}=\left(x_{2}, y_{2}\right), P_{3} \equiv\left(x_{3}, y_{3}\right), \text { and } P_{4}=\left(x_{4}, y_{4}\right) \text {. }
$$

The equation must be of the form (1),
therefore,

$$
\begin{array}{r}
A x_{1}^{2}+2 H x_{1} y_{1}+B y_{1}^{2}+2 G x_{1}+2 F y_{1}+C=0 \\
A x_{2}^{2}+2 H x_{2} y_{2}+B y_{2}^{2}+2 G x_{2}+2 F y_{2}+C=0 \\
A x_{3}^{2}+2 H x_{3} y_{3}+B y_{8}^{2}+2 G x_{3}+2 F y_{8}+C=0, \\
A x_{4}^{2}+2 H x_{4} y_{4}+B y_{4}^{2}+2 G x_{4}+2 F y_{4}+C=0 ; \\
H^{2}-A B=0,
\end{array}
$$

also,
The required ratios between the coefficients of equation (1) may be found from these equations.

## EXAMPLES ON CHAPTER XII

Without transforming the equations to other axes, find the center or the vertex, the axes, and the nature of the following conics:

1. $x^{2}+5 x y+y^{2}+8 x-20 y+15=0$;
2. $(x-y)^{2}+2 x-y=1$;
3. $3 x^{2}+2 y^{2}-2 x+y-1=0$;
4. $3 x^{2}-8 x y-3 y^{2}+x+17 y-10=0$;
5. $4 x^{2}-4 x y+y^{2}+4 a x-2 a y=0$;
6. $5 x^{2}+2 x y+5 y^{2}=0$;
7. $3 x^{2}+3 y^{2}+11 x-5 y+7=0$;
8. $x^{2}+2 x y-y^{2}+8 x+4 y-8=0$;
9. $y^{2}-x y-6 x^{2}+y-3 x=0$;
10. $y^{2}-x y-5 x+5 y=0$.

Trace the following conics:
11. $3 x^{2}+2 x y+3 y^{2}-16 y+23=0$;
12. $4 x^{2}+9 y^{2}+8 x+36 y+4=0$;
13. $3 x^{2}-3 y^{2}+8 x y-10 y+6 x+5=0$;
14. $(x-y)(x-y-6)+9=0$.
15. What conic is determined by the points $(0,3),(1,0),(2,1)$, $(-1,-3)$, and $(3,-3)$ ?
16. Find the equation of the parabola through the points (3, 2), $(1,8),(-6,8)$, and $(-2,8)$.
17. Find the equation of the conic through the points $(9,2),(6,8)$, $(3,2),(1,-2),(2,1)$.

## CHAPTER XIII

## HIGRER PLANE CURVES

184. Definitions. A curve, in Cartesian coördinates, whose equation is reducible to a finite number of terms, ench involv. ing only positive integer powers of the oobrdinates, is called an algebraic curve; all other curves aro called transcendental curves.

Algebraic eurves the ilegree of whose equations exceeds two, and all transcendental curves, are (if they lie wholly in a plane) called higher plane curves. On aceount of their great historical interest, and becauso of their frequent use in the Calculus, a few of these curves will be examined in the present chapter.

## I. ALGEBRAIC CLRVES

185. The cissoid of Diocles. The cissoid may be rlefined as follows: let $O F A K$ be a fixed circle of radius $a, O A$ a

[^44]diameter, $A T$ a tangent; draw any line as $O Q S$ through $O$, meeting the circle in $Q$ and the tangent in $S$, and on this line lay off the distance $O P=Q S$ : the locus of the point $P$, as the line $O S$ revolves about $O$, is the cissoid. *

From this definition, the equation of the cissoid, referred to the rectangular axes $O X$ and $O Y$, is readily derived.
 Let the coördinates of $P$ be $x$ and $y$, and let $C$ be the center of the circle so that

$$
O C=C A=C K=a .
$$

Since triangles OMP and $O N Q$ are similar,
$\therefore M P: O M:: N Q: O N$, . (1) and since $O P=Q S$, therefore
$N A=O M=x$; moreover, $\overline{N Q}{ }^{2}=O N \cdot N A=(2 a-x) x$.

Substituting these values in equation (1) gives

$$
\begin{equation*}
y: x:: \sqrt{(2 a-x) x}:(2 a-x), \tag{2}
\end{equation*}
$$

whence

$$
\begin{equation*}
y^{2}=\frac{x^{3}}{2 a-x}, \tag{3}
\end{equation*}
$$

which is the required rectangular equation of the cissoid.
The definition of the cissoid, as well as the equation just derived, shows that the curve is symmetric with regard to

[^45]the $x$-axis; that it lies wholly between the $y$-axis and the line $x=2 a$; that it passes through the estremities $F$ and $K$ of the diameter perpendicular to 0.1 ; and that it has two infinite branches to each of which the line $x=2 a$ is an asymptote.

Nork 1. The polar equation of the cinsoid referred to the initial line of. and prole $O$, is also easily foumal. Let the prolat coverdinates of $P$ he $p$ and 0 ; then,

$$
\begin{equation*}
\rho=O P=Q S=O S-O Q \tag{4}
\end{equation*}
$$

but

$$
O S=2 a \sec \theta, \text { and } O Q=2 a \cos \theta_{1}
$$

$\therefore \quad \rho=2 a \sec \theta-2 a \cos \theta=2 a(\sec \theta-\cos \theta)$,
i.e. $\quad \rho=2 a \tan \theta \sin \theta_{1}$.
which is the polar equation sought.
Sots 2. To "duplieate the cube" by means of the cissoid," extend $C K$ to $I$, making $\Pi K=C K=a$, draw the line $\| A$ putting the cisoid in , and draw the ordinate EJ. Since $C H=2 \mathrm{CA}$, therefore $\mathrm{EJ}=2 \mathrm{EA}$. but from equation (3),

$$
\begin{align*}
& E J^{2}=\frac{\overline{O E}}{E A}=\frac{\overline{O E}}{\frac{1 E J}{3}} ; \\
& \therefore E J^{3}=2 \overline{O E^{3}} . \tag{6}
\end{align*}
$$

Now let $m$ be the edge of any given cule, and let it be mequired to coniatruct a line $n$ such that the cuhe on $n$ shall be equal to the double of the eule on m. Construet $n$ so that
then
OE:EJ::m:n;
and, since $E J^{3}=2$. $0 E_{S^{2}}$, therefore $n^{8}=2 \mathrm{~m}^{8}$.
Nore 3. The cissoid may also be defined in either of the following ways: (1) as the locus of the point ( $P$ ) in which the chord $O Q S$ intermects that ordinate (ML) of the cirele which is equal to NQ: and (2) as the locus of the foot of the perpendicular let fall from the sertex of a paralula upon a tangent. The derivation of the equation of the curve taseal upon these definitions is left as an exercise for the student.

[^46]For Newton's method of drawing the cissoid by continuous motion, see Salmon's Higher Plane Curves, p. 183, or Larduer's Algebraio Geometry, p. 196.
186. The conchoid of Nicomedes.* The conchoid may be defined as follows : Let $P R P^{\prime} Q$ be a given circle of radius $a$ whose center $S$ moves along a fixed straight line $O X$; let $L K$ be a straight line drawn through a fixed point $A$ and the center $S$ of this moving circle, and let $P$ and $P^{\prime}$ be the intersections of this line and the circle; then the locus traced by $P$ (and by $P^{\prime}$ ) as $S$ moves along $O X$ is a conchoid.

This definition may also be stated thus: If $A$ is a fixed point, $O X$ a fixed line, and $S$ the point in which $O X$ is intersected by a line $L K$ revolving about $A$, then the locus of a point $P$ on $L K$, so taken that $S P$ is always equal to a given constant $a$, is a conchoid.

The fixed point $\boldsymbol{A}$ is called the pole, the constant parameter $a$ the modulus, and the fixed line $O X$ the directrix of the conchoid.

[^47]To derive the rectangular equation of the eobehoid draw $A O Y^{\circ}$ perpendicular, and $A / /$ parallel, $10 O X$, and let $O A=e$; let $P=(x, y)$ be any position of the generating point, and draw the orlinate HMP; then, from the similar triangles $A H P$ and SMP,

$$
\begin{array}{cc}
A / I: M P:: S M: M P \\
\text { i.e., } & x: y+c:: \sqrt{a^{2}-y^{2}}: y ; \\
& {\left[\text { since } S M=\sqrt{K H^{3}-M P^{3}}=\sqrt{a^{3}-y^{2}}\right],} \\
\text { whence } & x^{2} y^{3}=(y+c)^{2}\left(a^{3}-y^{2}\right),
\end{array}
$$

which is the equation sought.
The definition of the conchoid, as well as the equation just derived, shows that the curve is symmetric with regard to the $y$-axis ; that it lies wholly between the two lines $y=a$ and $y=-a$; and that it has four infinite branches to each of which the $x$-axis is an asymptote.

Nore 1. The polar equation of the conchoid. Let $A$ be the pule, $A Y$ the initial line, and $P \equiv(\rho, \theta)$ (or $P$ ) any position of the generating point: then
b.e.,

$$
\begin{gathered}
\rho=A P=A S \pm S P=O A \cdot \sec \theta \pm S P, \\
\rho=c \sec \theta \pm a_{0}
\end{gathered}
$$

which is the desired equation.
Nors 2. The conchoid may also be readily constructed by continuous motion as follows: By means of a slot in a ruler, fitting over a pin at A. the motion of the line $L . K$ is properly coutrolled; if now a guide pin at $\S$, and a tracing point at $P$, be aftached to this ruler, then the point $P$ will trace out the conchoid when the guide point $S$ is moved along the line OX.

Nots 3. By means of a conchoid, any given angle may be trimeted. 1 Let $A B C$ be any angle, on one zide (BA) take any diatanes, as $B H$, and

[^48]draw OHX perpendicular to the other side of the angle ( $B C$ ) ; then lay of $O K=2 B H$, and construct the conchoid $K E F$ with $B$ as pole and $2 B H=O K$ as modulus, and $O X$ as directrix. Draw $H L$ parallel to $B C$ and connect $B$ with $L$, then the angle $L B C=f A B C$; for, oin $D$, the

middle point of $M L$, to $H$, then $M L=O K=2 B H=2 H D$, and the three angles marked $\alpha$ are all equal, as are also the two marked $\beta$; moreover, $\beta=2 \alpha$, being the exterior angle of the triangle $H L D$, which proves that angle $L B C=1 A B C$.
187. The witch of Agnesi.* The witch may be defined as

Fig. 127. follows: Let $O K A Q$ be a given fixed circle of radius $a, O A$ a diameter, and $Q$ any point on the circle ; if now the ordinate $M Q$ be produced to $P$, so that

$$
\begin{equation*}
M Q: M P:: M A: O A, \ldots \tag{1}
\end{equation*}
$$

then the locus of $P$, as $Q$ moves around the circle, is the witch. To derive the rectangular equation of the witch, let $P \equiv(x, y)$ be any point on the curve; then, since

$$
M Q=\sqrt{O M \cdot M A}=\sqrt{x(2 a-x)},
$$

[^49]sulstituting in equation (1) gives
\[

$$
\begin{gather*}
\sqrt{x(2 a-x)}: y::(2 a-x): 2 a_{1} .  \tag{2}\\
y^{2}=\frac{4 a^{2} x}{2 a-x} \quad . \tag{3}
\end{gather*}
$$
\]

i.e.,
which is the equation sought.
The definition of the witeh, as well as the equation just derived, shows that the curve is symmetrical with regard to the $x$-axis; that it lies wholly between the $y$-axis and the line $x=2 a$; and that it has two infinite branches to each of which the line $x=2 a$ is an asymptote.
188. The lemniscate of Bernouilli. The lemniscate may be defined as follows: let $L T A R N A^{\prime} K$ be a rectangular hyperbola, $O$ its center, $O X$ and $O Y$ its axes, and $T E$ a tangent to the curve at any point $T$. Also let $O G$ be a perpendicular from the center upon this tangent, and let $P$ be the point of their intersection ; then the locus of $P$ as $T$ moves along the hyperbola is called the lemniscate.

To derive the rectangular equation of this curve, let $O A=a$, and let the coordinates of $T$ be $x_{1}$ and $y_{1}$; then the equation of the tangent $T E$ is

$$
\begin{equation*}
x_{1} x-y_{1} y=a^{2} \tag{1}
\end{equation*}
$$

hence the equation of $O Q$, the perpendicular upon this tangent (Art. 62), is

$$
\begin{equation*}
x_{1} y+y_{1} x=0 . \tag{2}
\end{equation*}
$$

[^50]Regrarding equations (1) and (2) as simultaneous, the $x$ and $y$ involved are the coordinates of the point $P$; moreover, since the point $T \equiv\left(x_{1}, y_{1}\right)$ is on the hyperbola, therefore

$$
\begin{equation*}
x_{1}^{2}-y_{1}^{2}=a^{2} . \tag{3}
\end{equation*}
$$

Eliminating $x_{1}$ and $y_{1}$ between equations (1), (2), and (3) gives

$$
\begin{equation*}
\left(x^{2}+y^{2}\right)^{2}=a^{2}\left(x^{2}-y^{2}\right) \tag{4}
\end{equation*}
$$

which is, therefore, the equation sought.

The definition of the lemniscate, as well as the equation just derived, shows that the curve is symmetrical with regard to both coördinate axes; that it lies wholly between the two lines whose equations are $x=-a$ and $x=+a$; that it passes through the origin and the two points $(-a, 0)$ and $(+a, 0)$; and that $y$ is never larger than $x$; hence the lemniscate is a limited closed curve as represented in Fig. 128.

[^51]fur then $x=\rho \cos \theta$ and $g=\rho \sin \theta$, and equation ( 1 ) at onces rediunes to
\[

$$
\begin{equation*}
\rho^{2}=a^{2}\left(\cos ^{2} \theta=\operatorname{nin}^{2} \theta\right)=a^{2} \cos 2 \theta, \tag{5}
\end{equation*}
$$

\]

which is therefore the reppuired puilar equation of the lemmiserate.
Equation (3) shows that: when $\theta=0, p=A$ a; when $0<45{ }^{\circ}, p$ has two equal trut ofpusite values, each of which is maller thian a; when $\theta=1.9, p=0$, i.e, the angle which the curre makes with the finitial line is $45^{\circ}$; when $45^{\circ}<\theta<133^{\circ}, \rho$ is imaginary; when $185^{\circ}<0<1$ wr, $\rho$ has two squal bot opposite values, each of which is smailer than a; and when $\theta=1$ :r, $\rho= \pm$ as. The curve, thercfore, consiats of two orals meeting in O, each lying in the same angle between the asymptotes of the hypertola as dons the corresponding branch of that curve, and these asymphotes ano tangent to the lemniseate at the point $O$.

Nore 2. If the two points $F_{1}$ and $F$ the so located that
$F_{1} O=O F=\frac{a}{2} \sqrt{2}$, and if $S E(r, y)$ he any point on the temmiseate
then $\quad F_{1} S=\sqrt{F_{1} M^{2}+M S^{2}}=\sqrt{\left(\frac{a}{2} \sqrt{2}+x\right)^{3}+y^{2}}$,
and $F S=\sqrt{\left(\frac{a}{2} \sqrt{2}-x\right)^{2}+y^{2}}$
Lenioe $F_{\mathrm{t}} \mathrm{S} \cdot F \mathrm{~S}=\sqrt{\left(\frac{a}{2} \sqrt{2}+x\right)^{2}+y^{2}} \cdot \sqrt{\left(\frac{a}{2} \sqrt{2}-x\right)^{2}+y^{2}}$

$$
=\sqrt{\left(x^{2}+y^{3}\right)^{2}-u^{2}\left(x^{2}-y^{3}\right)+\frac{a^{4}}{4}}=\frac{a^{2}}{2},[\text { by eq. (4) }] \text {, }
$$

i.e. $\quad F_{1} S \cdot F S=\frac{\sigma^{2}}{2}$

Hence the lemniseate may be defined as the locus of a point which moves so that the promluct of its distanees from 4 wo fined points is conatanif, and equal to the square of half the distance between the fixed proints (cf. foot-note, p. 315 ).

This delinition of the curve easily teads to the equation already A-rised; it also enalikes one to readily eomatruct the curve thins: with $P$ as center, and any convenient radius FS, aloserilue an are; then, with $f_{\text {}}$ as center, and a third propertinal to FS and $O F$ as radius, descrite arother are entting the first in $S$; thas intersention $S$ is a point on the fochs, and as many points was desifed may be construeted in the samo way
189.. The limacon of Pascal.* The limaçon may be defined as generated from a circle by adding a constant length to each of the radii vectores

Fio. 120 drawn from a point on its circumference as origin,proper account being taken of negative radii vectores. $\dagger$ E.g., let $O L A_{1} N$ be a given circle of radius $a, 0$ any point on it, $A_{1} A=k$ any constant ; then if any radius vector as $O P_{1}$ be drawn from $O$, and $P_{1} P$ $=A_{1} A=k$ be added to it, then $P$ is a point on the limaçon; and as $P_{1}$ is made to describe a circle, $P$ will trace the limaçon.

The polar equation of the curve is at once written down from this definition; for, if the diameter $O C X$ be taken as initial line, then the polar equation of the circle is

$$
\begin{equation*}
\rho=2 a \cos \theta, \tag{1}
\end{equation*}
$$

whence the polar equation of the limaçon is

$$
\begin{equation*}
\rho=2 a \cos \theta+k . \tag{2}
\end{equation*}
$$

If $k$ be taken equal to $a$, the radius of the given circle. this equation may be written in the more common form

$$
\begin{equation*}
\rho=a(1+2 \cos \theta) . \tag{3}
\end{equation*}
$$

[^52]The definition of the limagon, as well as the equation junt derived, shows that the curve is symmetrical with regard to the initial line, and that it has the form shown in Fig. 129.

Nots. The rectangular equation of the limagon for which $k=a$ is easily derived from equation (3). Chooning the intitial line and a perpendicular to it through $O$ as rectangular axes, so that $z=\rho \cos \theta$, and $y=\rho \sin \theta$, equation (3) becomes

$$
\begin{equation*}
\sqrt{x^{3}+y^{3}}=a+2 a \cdot \frac{s}{\sqrt{x^{3}+y^{3}}} \tag{t}
\end{equation*}
$$

Rationalizing equation ( 1 ) gives

$$
\begin{equation*}
\left(x^{2}+y^{2}-2 a x\right)^{2}=n^{2}\left(x^{2}+y^{2}\right) \tag{5}
\end{equation*}
$$

which is the usual form for the rectangular equation of the limascon.
189\%. The cardioid. The cardioid may be defined as a special case of the limaçon; viz., it is a limaçon in which the constant $k$, which is added to each of the radii vectores, is taken equal to the diameter of the fundamental circle. If in the equation of the limagon [Art. 189a, equation ( 2 )] the constant $k$ be taken equal to $2 a$, that equation becomes

$$
\begin{equation*}
\rho=2 a(1+\cos \theta) . \tag{1}
\end{equation*}
$$

which is the polar equation of the cardioid.
The more usual form in which the equation of the cardioid is written is

$$
\begin{equation*}
\rho=2 a(1-\cos \theta) \tag{2}
\end{equation*}
$$

but this amounts merely to turning the figure through $180^{\circ}$ in its own plane.

Nots 1. The rectangular equation of the cardioid is obtained as in Art. 159 a.

It is $\left(x^{4}+y^{2}+2 a x\right)^{2}=4 a^{2}\left(x^{2}+y^{5}\right)$.
The curve represented by equations (2) and (3) has the form shown in Fig. 1:50.

The cardioid is usually deffined as the lones traced by a point on a given circle $A K 1, h$, which rolls on an equal but fixed cireie $O M A_{1} H$. This inffimition alas leads to equations (2) and (i) already derived.

190. The Neilian, or semi-cubical, parabola.* This curve may be defined as follows : let HTASKL be a given parab-

Fig. 131 ola whose equation is

$$
\begin{equation*}
y^{2}=4 p x ; \tag{1}
\end{equation*}
$$

let TMS be any double ordinate of the curve, $T T_{1}$ a tangent at the point $T \equiv\left(x_{1}, y_{1}\right)$, and $A Q$ a perpendicular from the vertex upon this tangent; if $Q A$ intersects $T S$ in $P$, then the locus of $P$ as $T$ moves along the parabola is called a semi-cubical or Neilian parabola.
Its rectangular equation is derived as follows : the equation of $T T_{1}$ is

$$
\begin{equation*}
y_{1} y=2 p\left(x+x_{1}\right) \tag{2}
\end{equation*}
$$

hence the equation of $A Q$ is

$$
\begin{equation*}
y=-\frac{y_{1}}{2 p} x \tag{3}
\end{equation*}
$$

The equation of $T S$ is

$$
\begin{equation*}
x=x_{1} \tag{4}
\end{equation*}
$$

If now equations (3) and (4) be regarded as simultaneous, then $x$ and $y$ are the coördinates of the point $P$ in which the two lines intersect, and if $x_{1}$ and $y_{1}$ be eliminated by means of the equation

$$
\begin{equation*}
y_{1}^{2}=4 p x_{1} \tag{5}
\end{equation*}
$$

an equation connecting $x$ and $y$ is obtained.

[^53]Sulstituting for $x_{1}$ and $y_{1}$, in equation (5), their values in terms of $x$ and $y$ as foumd from equations (3) and (4). gives
i.e.,

$$
\begin{align*}
\frac{4 p^{2}}{x^{3}} y^{2} & =4 p x \\
y^{2} & =\frac{x^{3}}{p} \tag{6}
\end{align*}
$$

which is the equation sought.
This equation shows that the curve passes through the origin and is symmetrical with regard to the r-axis ; that it lies wholly on the same side of the $y$-axis as does the given parabola; and that it has two infinite branches.

## II. TRANSCENDENTAI. CTGVES•

191. The cycloid.t The cycloid (OP' $R A$ ) is the path traced by a point $P$ on the circumference of a circle ( $H$ NSP ${ }^{\prime}$ )

- A few very common transcendental curves have already been examimed in Clapter III; among these are the curve of ainem, the curve of tangents, and the logarithmic curve.
t Becanse of the clegance of its properties, and hecause of its numenus applieations in mechanies, the cyoluht le the mast lmpertant of the transeen. dontal curves. It has the adided historical linternat of lelugg the nevond curve that was rectified (cf. Art 190, foot-note). Its realileatoes was fint accom. phished by Sir Christopher Wren (1623-15:3) and prublished hy him in $16: 3$.
which rolls, without sliding, upon a fixed right line ( $O X$ ). The point $P$ is called the generating point; the circle PHNS, the generating circle; the points $O$ and $A$, the vertices; the line $E K$, perpendicular to $O A$ at its middle point, the axis; and the line $O A$, the base of the cycloid.

To derive the rectangular equation of the cycloid let $a$ be the radius of the generating circle, and $O X$ the fixed straight line on which it rolls; also let $P$ be the generating point, and let PNS be any position of the generating circle. Draw the radius $C P$, the ordinate $M P$, the line $P L$ parallel to $O X$, and the radius $O H$ to the point of contact of the generating circle and the line $O X$. Let $O X$ and $O Y$ (the perpendicular to it through $O$ ) be chosen as axes, and let $\theta$ be the angle $P C H$.

Then, if $P \equiv(x, y)$.

$$
\begin{aligned}
x=O M & =O H-M H \\
& =O H-P L
\end{aligned}
$$

$$
\begin{equation*}
=u \theta-a \sin \theta, \quad[\text { since } O H=\operatorname{arc} P H=a \theta] \tag{1}
\end{equation*}
$$

i.e., $\quad x=a(\theta-\sin \theta)$.

Similarly, $\quad y=a(1-\cos \theta)$.
Solving equation (2) for $\theta$ gives

$$
\begin{aligned}
\cos \theta & =\frac{a-y}{a} \\
\theta & =\cos ^{-1}\left(\frac{a-y}{a}\right)=\operatorname{sers}^{-1}\left(\frac{y}{a}\right)
\end{aligned}
$$

i.e.,
and substituting this value of $\theta$ in equation (1) gives

$$
\begin{equation*}
x=a \operatorname{vers}^{-1}\left(\frac{y}{a}\right)-\sqrt{2 a y-y^{2}} \tag{3}
\end{equation*}
$$

which is the rectangular equation sought.

Xotk 1. It is usually simpler to regarl equations (1) and (2) cogether
 and $g$ are both funetions of it.

Sots 2. The cycloid belougs to the kind of curves called roulettes. These curves are generated by a point which is invarially commected with a curve which rolls, without alliding, upon a given fixed curve.

If both the rolling and the fixed curves are circles, then the curve generated is designated by the general name of trochoid. It the geoerating point is on the circumficence of the rolling circle, and this circle rutts on the outsite of a fixed circle, theo the curve demerithed is called an epicycloid ; but if it rolls on the inside of the fixed circle, the generated curse is called a hypocycloid. The cycloid may be regaried either as an epicycloid or a hypocycloid, for which the fixed circle has its center at infinty and an infinite radius.
192. The hypocycloid. Let the hypocycloid APRSST ... lve traced by the point $P$ on the circumference of the circle $P Q R$, whose radius is $b$, and which rolls on the inside of the

fixed circle $A Q E$, whose radius is $a$. Also let $P \equiv(x, y)$ bo any position of the generating point. Draw the line $O O^{\prime} Q$, the ordinates $H O^{\prime}$ and $M P$, the radius $O P$, and the
line $K P$ parallel to $O A$, where $A$ is the point with which $P$ coincided when in its initial position. Let $O A X$ and $O Y$, the perpendicular to it through $O$, be chosen as coördinate axes; also let the angles $A O Q, P O^{\prime} Q$ and $O^{\prime} P K$ be desig. nated, respectively, by $\theta, \theta^{\prime}$ and $\phi$.

$$
\text { Then } \quad \begin{aligned}
O M & =O H+H M=O H+K P \\
& =O O^{\prime} \cos \theta+P O^{\prime} \cos \phi \\
& =O O^{\prime} \cos \theta+P O^{\prime} \cos \left(\theta^{\prime}-\theta\right),
\end{aligned}
$$

$$
\begin{equation*}
\left[\text { since } \phi=\theta^{\prime}-\theta\right] \tag{1}
\end{equation*}
$$

i.e. $\quad x=(a-b) \cos \theta+b \cos \left(\theta^{\prime}-\theta\right)$.

But since are $A Q=$ are $P Q$, therefore $a \theta=b \theta^{\prime}$, whence $\theta^{\prime}=\frac{a}{b} \theta$, and equation (1) becomes

$$
\begin{equation*}
x=(a-b) \cos \theta+b \cos \frac{(a-b) \theta}{b} \ldots \tag{2}
\end{equation*}
$$

Similarly, $y=(a-b) \sin \theta-b \sin \frac{(a-b) \theta}{b} \ldots$
Equations (2) and (3) are together the equations of the hypocycloid. A single equation representing the same curve may be found, as in the case of the cycloid (Art. 191), by eliminating $\theta$ between equations (2) and (3).

Note. If the radii of the circles he commensurable, i.e., if $b$ equals a fractional part of $a$, then the hypocycloid will be a closed curve; but if these radii are incommensurable, then the curve will not again pass through the initial point $A$.

In particular, if $a: b=4: 1$, then the circumference of the fixed circle is 4 times that of the rolling circle, and the hypocycloid becomes a closed curve of four arches, as shown in Fig. 134. In this case, equations (2) and (3) become, respectively,
$\left.\begin{array}{r}x=f a \cos \theta+\frac{1 a \sin 3 \theta}{} \\ \text { and } y \\ y \\ \mid a \sin \theta-1 a \sin 3 \theta\end{array}\right\} \cdot(1)$
But, by trigonometry.
$3 \cos \theta+\cos 3 \theta=4 \cos ^{-1} \theta$, and $3 \sin \theta-\sin 3 \theta=4 \sin ^{3} \theta$ 。 hechee erpuations (4) becotue and $\left.\quad \begin{array}{l}x=a \cos ^{8} \theta_{1} \\ y=a \sin ^{8} \theta_{i}\end{array}\right\} \cdots$ (5) whence $x^{3}+y^{3}=a^{1}$ - .
which ia the common form of the enpuation of the four-cusped hyprocycloid.

Tha. B4.

## SITRAIS

193. A spiral is a transcendental curve traced by a print which, while it revolves about a fixed point called the center, also continually recedes from this center, according to some definite law.

The portion of the spiral generated during one revolution of the tracing point is called a spire ; and the circle whose radius is the radius vector of the generating point at the end of the first revolution is called the measuring circle of the spiral. Thus, in Fig. 135, ABCDE' is the measuring circle, OQSUWA is the first spire, and AFHLAN is the seeond spire.
194. The spiral of Archimedes.t This curve is traced by a point which moves about a fixed point in a plane in sterh a

- If this equation be rationalized, it becomes

$$
27 a^{2} x^{2} y^{2}=\left(a^{4}-x^{2}-x^{4}\right)^{2}
$$

Although the hypocycloid is, in general, a mouscendental curve, is becomes algeliraie for particular values of the ratio of the radil of the circles.

T This curve is usually suppesed to have been dispovered by Conan, though its principal properties were taveatigated by the geometer in howe name it bears

Fic. 135.
way that any two radii vectores are in the same ratio as are the angles they make with the initial line.*

From this definition it follows that the equation of the curve is

$$
\begin{equation*}
\rho=k \theta, \ldots \tag{1}
\end{equation*}
$$

where $k$ is a constant.
This equation shows that the locus passes through the origin, and that the radius vector becomes larger and larger without limit as the number of revolutions increases without limit. Moreover, if ( $\rho_{1}, \theta_{1}$ ) be any point on the curve, and if $\left(\rho_{2}, \theta_{1}+2 \pi\right)$ be the corresponding point on the next spire, then

$$
\rho_{1}=k \theta_{1} \text { and } \rho_{2}=k\left(\theta_{1}+2 \pi\right)
$$

whence

$$
\rho_{2}=\rho_{1}+2 k \pi ;
$$

but $2 k \pi=O A$, hence the distance between the successive points in which any radius vector meets the curve is constant; it is always equal to the radius of the measuring circle. This follows also directly from the definition.

The locus of equation (1), for positive values of $\theta$ is represented in Fig. 135; for negative values of $\theta$ the locus is symmetrical with the part already drawn, the axis of symmetry being the line $L F$.
195. The reciprocal or hyperbolic spiral. This curve is traced by a point which moves about a fixed point in a plane in such a way that any two radii vectores are in the

[^54]same ratio as the reciprocals of the angles which they form with the initial line.

From this definition it follows that the equation of the curve is

$$
\begin{equation*}
\rho=\frac{k}{\theta}, \quad . \quad \tag{1}
\end{equation*}
$$

where $k$ is a constant.
This equation shows that the curve begins at infinity when $\theta=0$ and winds round and round the center, always approaching it, but never quite reaching it ; i.e., $p=0$ only after an infinite number of spires have been described.

Equation (1) also shows that the constant $k$ is the circumference of the measuring circle. For the radius of the measuring circle (Art. 193) is the radius vector of the generating point of the curve at the end of the first revolution, i.e., when $\theta=2 \pi$; but, from equation (1), this radius vector is $\frac{k}{2 \pi}$, and the circumference of the circle of which this is the radius is $k$.

Again, if $P \equiv(\rho, \theta)$ be any point on the locus of equation (1), then

$$
\begin{aligned}
\rho \theta & =k \\
& =\text { circumference of measuring circle ; }
\end{aligned}
$$

but $\rho \theta$ equals the length of the circular are described with radins $\rho$ and subtending an angle $\theta$, therefore the length of any circular are as MP, described about $O$, with radius $p$, and extending from the initial line to the curve, is equal to the circumference of the measuring circle.

Fro. 140:

The locus of equation (1), for positive values of $\theta$, is represented in Fig. 186.
196. The parabolic spiral. This curve is traced by a point which moves around a fixed point in a plane in such a way that the squares of any two radii vectores are in the same ratio as are the angles which they form with the initial line.
From this definition it follows that the equation of the curve is

$$
\begin{equation*}
\rho^{2}=k \theta, \quad \text {. . . } \tag{1}
\end{equation*}
$$

where $k$ is a constant.
This equation shows that the curve begins at the center when $\theta=0$, winds round and round

Fia. 137 this point, always receding from it, the radius vector becoming infinite when $\theta$ becomes infinite, i.e., when it has described an infinite number of spires.
The locus of equation (1), for positive values of $\rho$, is represented in Fig. 137.*
197. The lituus $\dagger$ or trumpet. This curve is traced by a point which moves around a fixed point in a plane in such a way that the squares of any two radii vectores are in the same ratio as the reciprocals of the angles which they form with the initial line.

From this definition it follows that the equation of the curve is

$$
\begin{equation*}
\rho^{2}=\frac{k}{\bar{\theta}} \quad . \quad . \tag{1}
\end{equation*}
$$

where $k$ is a constant.
This equation shows that the curve begins at infinity, when $\theta=0$, and winds round and round the center, always

[^55]approaching it, but nover quito reaching it, i.e., $\rho=0$ only after an infinite number of spires have been deseribed.

The locus of equation (1) is shown in Fig. 138; the heavy

Fia. 138
line being the part of the locus obtained from the positive values of $\rho$, while the dotted part belongs to the negative values of $\rho$.

Sotk. The four spirals just discusend, and whone forms are given in Figs. 13.5 to 13 K , are all included under the more general case of the curve defined by the equation

$$
\begin{equation*}
\rho=1 \cdot \theta^{\prime} ; \tag{2}
\end{equation*}
$$

if $n=1$, this is the spiral of Arehimedes; if $n=-1$, it is the hyperbolie spiral ; if $n=\frac{1}{2}$, it is the parabolic spiral; while if $n=-\frac{1}{6}$, it is tho lituus.
198. The logarithmic spiral. This curve is traced by a point which moves around a fixed point in a plane in sucis

[^56]a way that the logarithms of any two radii vectores are in the same ratio as are the angles which these lines form with the initial line.

From this definition it follows that the equation of the curve is

$$
\begin{equation*}
\log \rho=k \theta, \tag{1}
\end{equation*}
$$

where $k$ is a constant.
If $k$ be unity, and logarithms to the base $a$ be employed, this equation may be written in the form

$$
\begin{equation*}
\rho=a^{\theta} \tag{2}
\end{equation*}
$$

This equation shows that if $\theta=-\infty, \rho=0$; that $\rho$ increases from 0 to 1 , while
 $\theta$ increases from $-\infty$ to 0 ; and that $\rho$ continues to increase from 1 to $\infty$, while $\theta$ increases from 0 to $+\infty$; the curve has, therefore, an infinite number of spires.

If the constant $a$ equals 2 , then $\rho$ takes the values $\cdots \frac{1}{4}, \frac{1}{2}$, $1,2,4,8, \cdots$, when $\theta$ is assigned the values (in radians), $\cdots,-2,-1,0,1,2,3, \cdots$; Fig. 139 represents the locus of equation (2), $a$ being equal to 2 , for values of $\theta$ from $-2 \pi$ to +3 . In this figure $\angle F O E=\angle E O A=\angle A O B=\angle B O C$ $=\angle C O D=57^{\circ} .3$, and $O F=\frac{1}{4}, O E=\frac{1}{2}, O A=1, O B=2$, $O C Y=4$, and $O D=8$.

## PART II

## SOLID ANALYTIC GEOMETRY

## CHAPTER I

## COÖRDINATE SYSTEMS. THE POINT

199. Solid Analytic Geometry treats by analytic methods problems which concern figures in space, and therefore involves three dimensions. It is evident that new systems of coördinates must be chosen, involving three variables; and that the analytic work will therefore bo somewhat longer than in the plane geometry. On the other hand, since a plane may be considered as a special case of a solid where one dimension has the particular value zero, it is to bo expected that the analytic work with three coürdinate variables should be entircly consistent with that for two variables ; merely a simple extension of the latter. The student should not fail to notice this close analogy in all cases.

In the present chapter will be considered some simple and useful systems of coürdinates for determining the position of a point in space, some elementary problems concerning points, and the transformations of cobrdinates from one system to another. Later chapters will treat briefly of surfaces, particularly of planes and of surfaces of the second order, and of the straight line.
200. Rectangular coördinates. Let three planes be given fixed in space and perpendicular to each other, - the coördinate planes $X O Y, Y O Z$, and
 ZOX. They will intersect by pairs in three lines, $X^{\prime} X$, $Y^{\prime} Y$, and $Z^{\prime} Z$, also perpendicular to each other, called the coördinate axes. And these three lines will meet in a common point $O$, called the origin. Any three other planes, $L P, M P$, and $N P$, parallel respectively to these coördinate planes, will intersect in three lines, $N^{\prime} P, L^{\prime} P$, $M^{\prime} P$, which will be parallel respectively to the axes; and these three lines will meet in, and completely determine, a point $P$ in space. The directed distances $N^{\prime} P, L^{\prime} P$, and $M^{\prime} P$ thus determined, i.e., the perpendicular distances of the point $P$ from the coördinate planes, are the rectangular coördinates of the point $P$. They are represented respectively by $x, y$, and $z$. It is clear that

$$
\begin{aligned}
& x=N^{\prime} P=L L^{\prime}=N M^{\prime}=O M ; \\
& y=L^{\prime} P=M M^{\prime}=L N^{\prime}=O N ; \\
& z=M^{\prime} P=N N^{\prime}=M U=O L .
\end{aligned}
$$

It is generally convenient, however, to consider

$$
x=O M, y=M M^{\prime}, \text { and } z=M^{\prime} P .
$$

The point may be denoted by the symbol $P \equiv(x, y, z)$.
The axes may be directed at pleasure ; it is usual to take the positive directions as shown in the figure. Then the eight portions, or octants, into which space is divided by the coïrdinate planes, will be distinguished completely by the signs of the coördinates of points within them.

If the chomen corordinate planes were obligue to each ather, a set of oblique cotrdinates for any print in mpace might be found in an entirely analogons way.

Unless otherwise stated, rectangular coürdinates sill bee used in the subsequent work.
201. Polar coordinates. A second method of fixing the position of a point in space is by means of its distance and direction from a given fixed point. Let $O$ be a fixed proint in space, called the pole; and let $\rho$ be the distance from $O$ (w) any other point $P$. To give the direction of $\rho$, let $O R$ and $O S$ be two chosen directed perpendicular lines through $O$, determining the plane ROS; then the direction of $\rho$ will be
 given by the angle $\theta$ from the plane ROS to the plane POM. and the angle $\phi$ from the line $O S$ to $\rho$. 'The point $P$ ' is completely determined by the values of its radius vector $\rho$ and its vectorial angles $\theta$ and $\phi$, and may be denoted as $P \equiv(\rho, \theta, \phi)$. The elements $\rho, \theta, \phi$ are called the polar coordinates of the point $P$.

It is to be noted that for convenience the positive valnes of $\theta$ and $\phi$ are those for rotation in clockrise direction from ROS and OS, respectively. And although a given set of coorlinates fixes a single point, yet any point may have sixtec.n sets of coirdinates in a polar system, if, as usual, the ralues of the angles are less than $360^{\circ}$.
202. Relation between the rectangular and polar systems. If the axes $O R$ and $O . S$ of a polar system colncide with the axes $O X$ and $O Z$, ruspectively, of a rectangular sys.

Fio. 142
tem, the pole and origin therefore being coincident, then simple relations exist between the two sets of coördinates for any point. For, since $\angle O M M^{\prime}=90^{\circ}$ and $\angle O M^{\prime} P=90^{\circ}$, therefore $O M=O M^{\prime} \cos \theta$
$=O P \sin \phi \cos \theta$.

$$
M M^{\prime}=O M^{\prime} \sin \theta=O P \sin \phi \sin \theta,
$$

and
that is,

$$
M^{\prime} P=O P \cos \phi
$$

$$
\left.\begin{array}{l}
x=\rho \cos \theta \sin \phi,  \tag{1}\\
y=\rho \sin \theta \sin \phi, \\
z=\rho \cos \phi .
\end{array}\right\}
$$

Again, i.e.,
also
and

$$
\overline{O P^{2}}=O M^{\prime 2}+{\bar{M} P^{2}}^{2}=\overline{O M^{2}}+\overline{M M^{\prime}}+\bar{M}^{\prime} P^{2}
$$

$$
\rho^{2}=x^{2}+y^{2}+z^{2}
$$

$$
\tan \theta=\frac{y}{x}
$$

$$
\cos \phi=\frac{z}{\sqrt{x^{2}+y^{2}+z^{2} .}}
$$

The above relations give formulas for transformation from the one coördinate system to the other.
203. Direction angles: direction cosines. A third useful method of fixing a point in space is a combination of the two methods already considered. The axes of reference are chosen as in rectangular coördinates, and any point $P$ of space is fixed by its distance from the origin, called the radius vector, and the angles $a, \beta, \gamma$, which this radius

vector makes with the corirdimate axes, respectively. Themen angles are called the direction angles of the line OP, amil their cosines, its direction cosines. The proint may he con"isely denoted as the point $P$ ' $m(\rho, a, \beta, \gamma)$.

Simple equations connect these coobrdinates with those of the rectangular system; for, projecting $O P$ upon the axes $Q X, O E$, and $O Z$, respectively,

$$
\begin{equation*}
x=p \cos \mathrm{a}, \quad y=p \cos \beta, \quad 2=p \cos \gamma, \tag{8}
\end{equation*}
$$

and also, $p^{2}=x^{3}+y^{2}+z^{2}$, as in equations [2].
Moreover, the direction cosines are not independent, but are comnected by an equation ; for, by combining the above equations,
i.e.,

$$
\begin{gather*}
\rho^{2}=\rho^{2} \cos ^{2} a+\rho^{2} \cos ^{2} \beta+\rho^{2} \cos ^{2} \gamma \\
\cos ^{2} a+\cos ^{2} \beta+\cos ^{2} \gamma=1 . \tag{4}
\end{gather*}
$$

Such a relation was to have been expected, since only three magnitudes are necessary to determine the position of a point, and therefore the four numbers $\rho, u, \beta, \gamma$ could not be independent.

Any three numbers, $a, b, c$, are proportional to the direction cosines of some line; because if these numbers are considered as the coordinates of a point, then the direction cosines of the radius vector of that proint are, by eq. [3],
$\cos a=\frac{a}{\sqrt{a^{2}+b^{2}+c^{3}}}, \cos \beta=\frac{b}{\sqrt{a^{2}+b^{2}+c^{3}}}, \operatorname{ces} \gamma=\frac{c}{\sqrt{a^{2}+b^{2}+c^{2}}} .[5]$
These direction cosines are proportional to $a, b$, e; and are found by dividing $a, b, c$, respectively, by the same constant,

$$
\sqrt{a^{2}+b^{2}+c^{3}}
$$

Direction cosines are useful in giving the direction of any line in space. The direction of any line is the same as that of a parallel line throngh the origin, therefore the dirmetion of a line may be given by the direction angles of some
point whose radius vector is parallel to the line. Sometimes, as an equivalent conception, it is convenient to consider the direction angles as those formed by the line with three lines which pass through some point of the given line, and are parallel, respectively, to the coördinate axes.
204. Distance and direction from one point to another ; rectangular coördinates. A few elementary problems concerning points can now be easily solved;

Fig. 14. for example, the problem of finding the distance between two points. Let $O X, O Y, O Z$ be a set of rectangular axes, and $P_{1} \equiv\left(x_{1}, y_{1}, z_{1}\right)$ and $P_{2} \equiv\left(x_{2}, y_{2}, z_{2}\right)$ be two given points. Then the planes through $P_{1}$ and $P_{2}$, parallel, respectively, to the coördinate planes, form a rectangular parallelopiped, of which the required distance $P_{1} P_{2}$ is a diagonal. From the figure,
since $\quad \angle P_{1} Q P_{2}=90^{\circ}$ and $\angle M_{1}^{\prime} R M_{2}^{\prime}=90^{\circ}$,
therefore

$$
\begin{aligned}
\overline{P_{1} P_{2}^{2}} & =\overline{P_{1} Q^{2}}+\overline{Q P_{2}^{2}}=\overline{M_{1}^{\prime} M_{2}^{\prime}}+\overline{Q P_{2}^{2}} \\
& =\overline{M_{1}^{\prime} R^{2}}+\overline{R M_{2}^{\prime}}{ }^{2}+\overline{Q P_{2}^{2}} \\
& =\left(x_{2}-x_{1}\right)^{2}+\left(y_{2}-y_{1}\right)^{2}+\left(z_{2}-z_{1}\right)^{2}
\end{aligned}
$$

That is, if $d$ be the required distance,

$$
\begin{equation*}
a=\sqrt{\left(x_{2}-x_{1}\right)^{2}+\left(y_{2}-y_{1}\right)^{2}+\left(z_{2}-z_{1}\right)^{2}} \tag{6}
\end{equation*}
$$

Moreover, since the direction of the line $P_{1} P_{2}$ is given by the angles $\alpha, \beta, \gamma$, which it makes, respectively, with the lines $P_{1} X^{\prime}, P_{1} Y^{\prime}$, and $P_{1} Z^{\prime}$, drawn through $P_{1}$ parallel to the
axm, therefore the projection of $d\left(=P_{1} P_{2}\right)$ upon these limes in turn gives

$$
P_{1} P_{8} \cos \varepsilon=P_{1} X^{\prime}, P_{1} P_{2} \cos \beta=P_{1} Y^{\prime \prime}, P_{1} P_{3} \cos \gamma=I_{1} Z^{\prime} \text {, }
$$

$$
\text { i.e.. } d \cos a=x_{2}-x_{3}, \quad d \cos \beta=y_{3}-y_{1}, \quad d \cos \gamma=z_{3}-z_{1} \text {; }
$$

and, finally,

$$
\cos \alpha=\frac{x_{2}-x_{1}}{d}, \cos \beta=\frac{y_{z}-y_{1}}{d}, \quad \cos \gamma=\frac{z_{z}-z_{1}}{d} \ldots \text { [ग] }
$$

These equations give the required direction angles of $P_{1} P_{\text {r }}$.
205. The point which divides in a given ratio the straight line from one point to another. Let $P_{1} \equiv\left(x_{1}, y_{1}, z_{1}\right)$ and $P_{2} \equiv\left(x_{2}, y_{2}, z_{2}\right)$ le two given points, and let $P_{8} \equiv\left(x_{8}, y_{8}, z_{8}\right)$ be a third point which divides the line $P_{1} P_{3}$ in the given ratio $\frac{m_{1}}{m_{2}}$, so that $\frac{P_{1} P_{3}}{P_{3} P_{2}}=\frac{m_{1}}{m_{2}}$.

Fio. 145

Let $P_{1} P_{8}=d_{1}$, and $P_{8} P_{2}=d_{2}$; then by Art. 204, if $a, \beta, \gamma$ be the direction angles of $P_{1} P_{8}$

$$
\cos \alpha=\frac{x_{3}-x_{1}}{d_{1}}=\frac{x_{2}-x_{3}}{d_{2}} ; \therefore \frac{x_{3}-x_{1}}{x_{2}-x_{3}}=\frac{d_{1}}{d_{2}}=\frac{m_{1}}{m_{2}},
$$

and

Similarly,
and

$$
\left.\begin{array}{l}
x_{3}=\frac{m_{1} x_{2}+m_{2} x_{1}}{m_{1}+m_{2}} \\
y_{3}=\frac{m_{1} y_{2}+m_{2} y_{1}}{m_{1}+m_{2}}  \tag{8}\\
z_{3}=\frac{m_{1} z_{2}+m_{9} z_{1}}{m_{1}+m_{2}}
\end{array}\right\}
$$

It will be noticed, as in the similar prohlem in Part I, Art. 30, that if $P_{8}$ divides the line externally, the ratio $\frac{m_{3}}{m_{3}}$ must be negrative; and the above formulas still apply.

If $P_{3}$ bisects the line $P_{1} P_{2}$, formulas [8] take the simpler forms

$$
x_{3}=\frac{x_{1}+x_{2}}{2}, \quad y_{3}=\frac{y_{1}+y_{2}}{2}, \quad z_{3}=\frac{z_{1}+z_{2}}{2} \ldots .[9]
$$

206. Angle between two radii vectores. Angle between two lines. Let $P_{1} \equiv\left(\rho_{1}, \alpha_{1}, \beta_{1}, \gamma_{1}\right)$ and $P_{2} \equiv\left(\rho_{2}, \alpha_{2}, \beta_{2}, \gamma_{2}\right)$ be two given points, and $\theta$ the angle included by the radii vectores $\rho_{1}$ and $\rho_{2}$. Then the pro-
 jections upon $O P_{1}$ of the line $O P_{2}$ and of the broken line $O M_{2} M_{2}^{\prime} P_{2}$ are equal (Art. 17); hence,

$$
\begin{aligned}
& \text { proj. } O P_{2}=\text { proj. } O M_{2} M_{2}^{\prime} P_{2} \\
& \text { i.e., } \quad \rho_{2} \cos \theta=O M_{2} \cos \alpha_{1} \\
& +M_{2} M_{2}^{\prime} \cos \beta_{1}+M_{2}^{\prime} P_{2} \cos \gamma_{1}
\end{aligned}
$$

But

$$
O M_{2}=\rho_{2} \cos \alpha_{2}
$$

$$
M_{2} M_{2}^{\prime}=\rho_{2} \cos \beta_{2}, \text { and } M_{2}^{\prime} P_{2}=\rho_{3} \cos \gamma_{2}
$$

hence,
$\rho_{2} \cos \theta=\rho_{2} \cos \alpha_{2} \cos \alpha_{1}+\rho_{2} \cos \beta_{2} \cos \beta_{1}+\rho_{3} \cos \gamma_{2} \cos \gamma_{13}$
i.e., $\quad \cos \theta=\cos a_{1} \cos a_{2}+\cos \beta_{1} \cos \beta_{2}+\cos \gamma_{1} \cos \gamma_{2}, \quad$ [10] and this relation determines the required angle $\theta$.

It follows, since any two straight lines in space have their directions given by the direction angles of radii vectores which are parallel to them, respectively, that formula [10] applies as well to the angle $\theta$ between any two straight lines in space, whose direction angles are given.

Two special cases arise, that of parallel and that of perpendicular lines. If the two given lines are parallel, evidently

$$
\begin{equation*}
a_{1}=a_{2}, \beta_{1}=\beta_{2}, \gamma_{1}=\gamma_{2} ; \tag{11}
\end{equation*}
$$

and formula [10] reduces to eq. [4]. If the lines are prerpendicular, cos $\theta=0$, and eq. [10] reduces to

$$
\cos a_{1} \cos a_{2}+\cos \beta_{1} \cos \beta_{2}+\cos r_{1} \cos r_{8}=0 . . . \cdot[1 \eta]
$$

207. Transformation of coordinates; rectangular systems. The relations found in Art. 202 to exint between rectangle. lar and polar coordinates of a point may be used as formulas of transformation from one system to the other if the origin, the pole, and the reference ases are coincident. Two other simple transformations may be useful, (1) from one set of rectangular axes to a parallel set, that is, a change of origin only ; and ( 2 ) from one set of rectangular axes to another set through the same origin, i.e., a change of dircefion of axes. Then any transformation between rectangular and polar systems can be performed by a combination of these three elementary transformations.
(1) Change of origin only. Let the new origin be the point $O^{\prime}=(h, k, j)$; then, constructing the coorrdinates of any

Fis $14 \%$ point $P$ with reference to each set of coördinate planes, it is evident, by analogy with Art. 71, that

$$
\begin{equation*}
x=x^{\prime}+h, \quad y=y^{\prime}+k, \quad z=z^{\prime}+j . \tag{13}
\end{equation*}
$$

(2) Change of direction of ares. Let a second set of reetangular axes, $O X^{\prime}, O Y^{\prime}, O Z^{\prime}$, have the direction angles $\propto_{1}$. $\beta_{1}, \gamma_{1}, \mu_{2}, \beta_{2}, \gamma_{3}$, and $\alpha_{3}, \beta_{8}, \gamma_{3}$, respectively, with the old axes $O X, O Y, O Z$.

Fio. 148

Then if the coördinates of any point $P$ in the two systems are

$$
\begin{aligned}
& x=O M \\
& y=M M^{\prime} \\
& z=M^{\prime} P \\
& x^{\prime}=O Q \\
& y^{\prime}=Q Q^{\prime} \\
& z^{\prime}=Q^{\prime} P
\end{aligned}
$$

and
then projections of $O P$ and the broken line $O Q Q^{\prime} P$ upon $O X$, $O Y, O Z$, in turn, will be equal ; hence,

$$
\left.\begin{array}{l}
x=x^{\prime} \cos \alpha_{1}+y^{\prime} \cos \alpha_{2}+z^{\prime} \cos \alpha_{3},  \tag{14}\\
y=x^{\prime} \cos \beta_{1}+y^{\prime} \cos \beta_{2}+z^{\prime} \cos \beta_{3}, \\
z=x^{\prime} \cos \gamma_{1}+y^{\prime} \cos \gamma_{2}+z^{\prime} \cos \gamma_{3} \cdot
\end{array}\right\}
$$

These formulas are for transformation from the first system to the second. But, also, by projecting $O P$ and $O M M^{\prime} P$ upon $O X^{\prime}, O Y^{\prime}, O Z^{\prime}$, respectively,

$$
\left.\begin{array}{l}
x^{\prime}=x \cos \alpha_{1}+y \cos \beta_{1}+z \cos \gamma_{1} \\
y^{\prime}=x \cos \alpha_{2}+y \cos \beta_{2}+z \cos \gamma_{2}  \tag{15}\\
z^{\prime}=x \cos \alpha_{8}+y \cos \beta_{3}+z \cos \gamma_{3}
\end{array}\right\}
$$

and these formulas are for the reverse transformation, from the second system to the first.

Note. It is to be remembered that in the transformations of [14] and [15], twelve conditions exist, by eq. [4] and eq. [12], three of each of the following types,

$$
\begin{aligned}
& \cos ^{2} a_{1}+\cos ^{2} a_{2}+\cos ^{2} a_{3}=2 \\
& \cos ^{2} a_{1}+\cos ^{2} \beta_{1}+\cos ^{2} \gamma_{1}=1 \\
& \cos a_{1} \cos a_{2}+\cos \beta_{1} \cos \beta_{2}+\cos \gamma_{1} \cos \gamma_{2}=0 \\
& \cos a_{1} \cos \beta_{1}+\cos a_{2} \cos \beta_{2}+\cos a_{3} \cos \beta_{3}=0 .
\end{aligned}
$$

These equations are not independent, however, but reduce to six independent equations.

It is clear, by reasoning similar to that of Art. 75, Part I. that none of the transformations [13], [14], and [15], besthes segparately nor in combination, can alter the degree of an equation to which they may be applied.

## EXAMPLES ON CHAPTER I

1. Prove thint the triangle formed ly joining the pointes $(1,2,3)$, $(2,2,1)$, and (3, 1, 2), in pains, is equilateral.
2. The direction cesines of a straight tine are proportional to $1,2,3$; find their values.
3. Find the angle leetween two straight lines whome direction comines are propertional to $2,2,2$, and $5,-1,7$, reppectively.
4. The rectangular coourdinates of a point are $(\sqrt{3}, 1,2 \sqrt{3})$; find its polar coürdinates.
5. The polar coürdinates of a point are $\left(3, \frac{\pi}{6}, \frac{\pi}{3}\right)$; find its rectangular coürdinatos.
6. Express the distanco between two points in termas of their polar coobrdinates.
7. Find the coürdinates of the points dividing the lime from $(-2,-3,1)$ to $(3,-2,4)$ externally and internally in the ratio $2: 5$.
a. What is the length of a line whose projections on the courdinate axes are 4, 1, 3, respectively ?
8. Find the radins veetor, and its direction cosines, for each of tho pwinte $(-7,1,5),(1,-1,-2),(a, 0, b)$.
9. Find the center of gravity ${ }^{\circ}$ of the triangle of Ex. 1.
10. Find the direction angles of a straight line which makes equal angles with the three coordinate axes.
11. A straight line makes the angle $30^{\circ}$ with the xaxis, and $75^{\circ}$ with the saxis. At what angle does it meet the $y$-axis?
12. Prove analytically that the straight lines juining the midj-wints of the opprosite eigos of a tetrahedron pass through a commun point, and are bisected by it.
13. Prove amalytically that the straight lines joining the midpowints of the opprosite sides of any quadrilateral pass through a common point, and are liseeted by it.

## CHAPTER II

## THE LOCUS OF AN EQUATION. SURFACES

208. Attention has been called to the close analogy between the corresponding analytical results for the geometry of the plane and of space. It is evident that in geometry of one dimension, restricted to a line, the point is the elementary conception. Position is given by one variable, referring to a fixed point in that line ; and any algebraic equation in that variable represents one or more points. In geometry of two dimensions, however, it has been shown that the line may be taken as the fundamental element. Position is given by two variables, referring to two fixed lines* in the plane; and any algebraic equation in the two variables represents a curve, i.e., a line whose generating point moves so as to satisfy some condition or law. Correspondingly, in geometry of three dimensions the surface is the elementary conception. Position is given by three variables, referring to three fixed surfaces, since any point is the intersection of three surfaces ; $\dagger$ and it can be shown that any algebraic equation in three variables represents some surface.
[^57]The study of the spuecial equations of first and secomal degree will be taken up in the two sucoeveling chapters. Here it is clesired to show that an algelonaie equation is three variables represents a surface, and to consider brielly two simple classes of surfaces : (1) cylinders, i.e., surfaces which are generated by a straight line moving parallel to a fised straight line, and always intersecting a fixed curve; and (2) surfaces of revolution, i.e., surfaces generated by revolving some plane curve about a fixed straight line lying in its plane.
209. Equations in one variable. Planes parallel to coordinate planes. From the definition of rectangular couralinates, it follows that the equations

$$
x=0, y=0, z=0,
$$

represent the coirdinate planes, respectively, and that any algebraic equation in one variable and of the first degree represents a plane parallel to one of them. Similarly, an equation in one variable and of degree $n$ will represent $n$ such parallel planes, either real or imaginary. For, the first member of any such equation, as

$$
\begin{equation*}
p_{0} x^{n}+p_{1} x^{n-1}+p_{3} x^{n-2}+\cdots+p_{0-1} x+p_{0}=0_{2} \ldots \tag{1}
\end{equation*}
$$

can be factored into $n$ linear factors, real or imaginary,

$$
p_{0}\left(x-x_{1}\right)\left(x-x_{2}\right)(\cdots)\left(x-x_{n}\right)=0 ;
$$

and by the reasoning of Part I. Art. 40, eq. (\%) will represent the loci of the $n$ equations

$$
x-x_{1}=0, x-x_{3}=0, \cdots, x-x_{0}=0
$$

each of which is a plane, parallel to the $y$-plane, and real if the corresponding root is real. In the same way, an equa-
tion in $y$ or 2 only will represent planes parallel to the $z x$ - or $x y$-plane.

Any algelraic equation in one variable represents one or more planes parallel to a coördinate plane.

It follows at once by Art. 39, that two simultaneous equations of the first degree in one variable represent the intersection of two planes parallel to coördinate planes; therefore, represent a straight line parallel to the coördinate axis of the third variable; e.g., $y=b, z=c$, considered as simultaneous equations, represent a straight line parallel to the $x$-axis.
210. Equations in two variables. Cylinders perpendicular to coordinate planes. Consider the equation

$$
\begin{equation*}
2 x+3 y=6 \tag{1}
\end{equation*}
$$

with two variables only. In the $x y$-plane it represents a straight line $A B$. If, now, from any point $P$ of $A B$ a

straight line be drawn parallel to the $z$-axis, the $x$ and $y$ coördinates of every point $Q$ on this line will be the same as for $P$, and therefcre satisfy equation (1). Moreover, if the line $P Q$ moved along $A B$, and always parallel to the $z$-axis,
still the coordinases of every point in it satisfy equation (1). As the line $P Q$ is thus moved, it traces a plane surface per. [embicular to the ry-plane ; amd, ns evidently the conerdinates of a point not on this surface do not satisfy equation (1). this plane is the locus of equation (1).

Again: the equation

$$
\begin{equation*}
y^{2}+z^{2}=r^{2} \quad . \quad . \quad . \tag{2}
\end{equation*}
$$

represents in the $y z$-plane a circle. It is therefore satisfied by the coordinates of any point $Q$, in a line parallel to the $x$-axis, through any point $P$ of this circle; and also by the coürdinates of $Q$ as this line $P Q$ is moved, parallel to

the $a$-axis and along the circle. The circular cylinder thus traced by the line $P Q$, perpendicular to the $y z$-plane, is the locus of the given equation.

Similarly, it may be shown that the locus of the equation

$$
\begin{equation*}
\frac{a^{2}}{a^{2}}-\frac{z^{2}}{b^{2}}=1 \tag{8}
\end{equation*}
$$

is a cylindrical surface traced by a straight line parallel to the $y$-axis, and moving along the hyperbola whose equation in the $r z$-plane is equation (8). And, in general, it is clear by analogy that any algeloraie equation in two variahles represents a cylindrical surface whose elements are parallel to the
axis of the third variable, and having its form and position determined by the plane curve represented by the same equation.

As a direct consequence, it is clear that if a cylinder has its axis parallel to a coördinate axis, a section made by a plane, perpendicular to that axis, is a curve parallel to and equal to the directing curve on the coördinate plane, and is represented in the cutting plane by the same equation. Thus, the section of the elliptical cylinder whose equation is $3 x^{2}+y^{2}=5$, cut by the plane $z=7$, is an ellipse equal and parallel to the ellipse whose equation is $3 x^{2}+y^{2}=5$.
211. Equations in three variables. Surfaces. A solid figure has the distinctive property that it can be cut by a straight line in an infinite number of points, while a surface or line can, in general, be cut in only a finite number. A line has the distinctive property that it can be, in general, cut by a plane in only one point, while a surface may be cut in a curve. To show that the locus of an algebraic equation in three variables is, in general, a surface, it is sufficient to show that, in general, a plane will cut it in a curve, while a straight line will cut it in a finite number of points.

Let the given equation be

be a plane parallel to the $x y$-plane. The points of intersection of these two loci will be on the locus of the equation

$$
\begin{equation*}
f(x, y, c)=0 ; \tag{3}
\end{equation*}
$$

and, by Art. 210, they lie, therefore, upon a plane curve, cut from the cylinder whose equation is (3), by the plane whose equation is (2). Hence the locus of equation (1) is not a line.

$$
\begin{equation*}
\text { Again, let } \quad y=1, z=0 \quad \text {. . . } \tag{4}
\end{equation*}
$$

Ine the equations of a straight line (Art. 209), parallel to the $x$-axis. The points of intersection of locus (1) and the line (4) will be also on the locus of the equation

$$
\begin{equation*}
f(x, b, c)=0 ; \tag{5}
\end{equation*}
$$

which, since the equation is in one variable, of finite degree, will represent a finite number of planes parallel to the $y z$ plane, and therefore having a finite number of points of intersection with the line (4). Hence the locus of equation (1) is not a solid.

Therefore, the locus of any algebraic equation in three variables is a surface.
212. Curves. Traces of surfaces. Two surfaces intersect in a curve in space, and since every algebraic equation in solid analytic geometry represents a surface, a curve may be represented analytically by the two equations, regarded as simultaneous, of surfaces which pass throngh it. Thus it has been seen that the equations $y=b, z=c$ separately represent planes, but considered as simultaneous represent the straight line which is the intersection of those planes. But by the reasoning of Art. 41, the given equations of a curve may be replaced by simpler ones which represent other surfaces passing through the same curve. In dealing with curves it is often useful to obtain, from the equations given, equations of cylinders through the same curve; i.e.. it is generally useful to represent a curve by two equations each in two variables only.

Example: The curre of intensection of the iwo surfaces,

$$
\text { (1) } x^{2}+y^{2}+z^{3}-25=0 \text { and (2) } x^{3}+y^{2}-10=0 \text {, }
$$

is also the intersection of the surfaces

$$
\begin{equation*}
x^{2}+y^{2}+z^{2}-25-\left(x^{2}+y^{2}-10\right)=0, \text { i.e., } z= \pm 3, \tag{3}
\end{equation*}
$$

with the surface (2). The curve is therefore composed of two circles of radius 4 , parallel to the $x y$-plane at distances +3 and -3 from it.

Conversely, the curves of intersection of a surface with the coördinate planes may be used to help determine the nature of a surface. These curves are called the traces of the surface.

Thus, the surface $x^{2}+y^{2}+z^{2}=25$ has the traces
on the $y z$-plane, where $x=0, y^{2}+z^{2}=25$; on the $z x$-plane, where $y=0, x^{2}+z^{2}=25$; on the $x y$-plane, where $z=0, x^{2}+y^{2}=25$.

Each of these traces is a circle of radius 5, about the origin as center; the surface is a sphere of radius 5 with center at the origin.

Since three surfaces in general have only one or more separate points in common, the locus of three equations, considered as simultaneous, is one or more distinct points.
213. Surfaces of revolution. Analogous to the cylinders are the surfaces traced by revolving any plane curve about a straight line in the plane as axis. From the method of formation, it follows that each plane section perpendicular to the axis is a circle, - the path traced by a point of the generating curve as it revolves; and the radius of the circle is the distance of the point from the axis in the plane before revolution begins. These facts lead readily to the equation of any surface of revolution, as a few examples will show.
(a) The cone formed by revolving about the z-axis the line

$$
\begin{equation*}
2 x+3 z=15 \tag{1}
\end{equation*}
$$

Any point $P$ of the line (1) traces during the revolution a circle of radius $L P$. parallel to the xy-plane. The equation of that path is

$$
a^{3}+y^{3}=L P^{3} .
$$

But in the $x z$-plane, before revorution is begun, $L P$ is the abscissa $x$ of $P$; hence, by equation (1),

$$
\overline{L P}=x=\frac{15-3 z}{2} ;
$$

so that the equation of the path of $P$ is

$$
\begin{equation*}
x^{2}+y^{2}=\frac{(15-3 z)^{2}}{4} \tag{2}
\end{equation*}
$$

But $P$ is any point of line (1); hence equation (2) is satisfied by every point of the line, and represents the surface generated by the line, which is the required conical surface.
(b) The sphere formed by revolving about the z-axis the circle

$$
\begin{equation*}
x^{2}+2^{2}=25 \text {. . . . } \tag{8}
\end{equation*}
$$

In this case, any point $P$ of the curve traces during the revofution a circle of radius $N P$, parallel to the ry-plane. The equation of this path is therefore

$$
x^{2}+y^{2}=N P^{2} .
$$

Fig. 152.

But in the $x z$-plane, by equation (3)

$$
N P=x=\sqrt{25-z^{2}} .
$$

Hence, substituting above,

$$
\begin{equation*}
x^{2}+y^{2}=25-z^{2} \tag{4}
\end{equation*}
$$

i.e., $x^{2}+y^{2}+z^{2}=25$;
which is the equation of the required spherical surface.
(c) The surface formed by revolving about the x-axis the curve

$$
\begin{equation*}
z^{2}=(x-1)(x-2)(x-3)[\text { cf. Art. } 37,(4)] \tag{5}
\end{equation*}
$$

Any point $P$ of the generating curve traces a circle parallel to the $y z$-plane, with a radius $M P$ equal to the $z$-abscissa in equation (5). Hence the equation of its path is

$$
y^{2}+z^{2}=\overline{M P}^{2}
$$

i.e., $y^{2}+z^{2}=(x-1)$
$(x-2)(x-3), \ldots(6)$
which is the equation of the required surface.
(d) Of the various surfaces of revolution

Fio. 168.
those of particular interest are generated by revolving about their axes the various conic sections, giving the cones, spheres, paraboloids, ellipsoids, and hyperboloids of revolution.

The student may verify the equations of the following surfaces : *

The sphere: with center at the origin, and radius $r$,

$$
\begin{equation*}
x^{2}+y^{2}+z^{2}=x^{2} \tag{7}
\end{equation*}
$$

with center at $(a, b, e)$, by Art. 207, eq. (i) becomes

$$
\begin{equation*}
(x-a)^{2}+(y-b)^{2}+(z-e)^{2}=r^{3} . \tag{8}
\end{equation*}
$$

The cone: the surface generated by the right line $2=m x+c$. rotated about the $z$-axis,

$$
\begin{equation*}
x^{2}+y^{2}=\frac{(z-c)^{2}}{m^{2}} \tag{9}
\end{equation*}
$$

The oblate spheroid: the surface generated by the ellipse $\frac{x^{2}}{a^{2}}+\frac{z^{2}}{b^{2}}=1$, rotated about the minor axis,

$$
\begin{equation*}
\frac{x^{2}}{a^{2}}+\frac{y^{2}}{a^{2}}+\frac{z^{2}}{b^{3}}=1 . \tag{10}
\end{equation*}
$$

The prolate spheroid: the surface generated by the ellipse $\frac{2^{2}}{l^{3}}+\frac{z^{2}}{u^{2}}=1$, rotated about the major axis,

$$
\begin{equation*}
\frac{x^{2}}{b^{2}}+\frac{y^{2}}{b^{2}}+\frac{a^{2}}{a^{2}}=1 \tag{11}
\end{equation*}
$$

The hyperboloid of one nappe: the surface generated by the hyperbola $\frac{x^{3}}{a^{2}}-\frac{z^{3}}{b^{2}}=1$, rotated about the conjugate axis,

$$
\begin{equation*}
\frac{x^{2}}{a^{3}}+\frac{y^{2}}{a^{3}}-\frac{x^{3}}{b^{2}}=1 \tag{12}
\end{equation*}
$$

The hyperboloid of two nappes: the surface generated by the hyperbola $\frac{x^{3}}{a^{3}}-\frac{z^{2}}{b^{2}}=1$, rotated about the cransverse axis,

$$
\begin{equation*}
\frac{x^{2}}{a^{2}}-\frac{y^{2}}{b^{2}}-\frac{x^{2}}{b^{2}}=1 . \tag{18}
\end{equation*}
$$

[^58]The paraboloid of revolution: the surface generated by the parabola $x^{2}=4 p z$, rotated about its axis,

$$
\begin{equation*}
x^{2}+y^{2}=4 p z \tag{14}
\end{equation*}
$$

## EXAMPLES ON CHAPTER II

What is the locus of each of the following equations?

1. $x^{2}-6 x+9=0$.
2. $2 x+4=0$.
3. $x^{3}-2 x y+y^{2}+2 x-2 y+1=0$.
4. $a x^{2}+b x y+c y^{2}=0$.
5. $4 y z+6 y-8 z+1=0$.
6. $z^{2}-9 y=9$.

What are the curves of intersection of the surfaces represented by the equations
7. $y+1=0,3 x^{2}+3 y^{2}+3 z^{2}=20$ ?
8. $x^{2}-y^{2}=0, \quad z=a$ ?
9. $x^{2}+y^{2}+z^{2}=9, \quad 4 x^{2}+y^{2}=4$ ?
10. $9\left(x^{2}+y^{2}\right)-z^{2}=25-10 z, \quad z= \pm 5$ ?
11. $3 x^{2}-4 y^{2}-z^{2}=12, \quad \frac{x^{2}}{9}+\frac{y^{2}}{16}=1$ ?

Determine the traces upon the coorrdinate planes of the following surfaces:

$$
\text { 12. } x^{2}+y^{2}+4 z^{2}=25 ; \quad \text { 13. } 3 x^{2}-4 y^{2}-z^{2}=12 .
$$

Find the equation of
14. the paraboloid of revolution one of whose traces is $y^{2}=-5 x+3$.
15. the cone of revolution one whose traces is $y=-5 x+3$ and whose axis is the axis of $y$. Find its vertex.
16. the oblate spheroid one of whose traces is $\frac{z^{2}}{2}+\frac{x^{2}}{3}=1$.
17. the prolate spheroid one of whose traces is $\frac{y^{2}}{7}+\frac{z^{2}}{9}=1$.
18. the surface of revolution whose axis is the axis of $x$ and one of whose traces is $x^{2} y-1=0$.
19. the hyperboloid of two nappes one of whose traces is $16 x^{2}-9 z^{3}=1$.
20. the sphere described about the major axis of the ellipse $4 x^{2}+9 y^{2}-24 x=0$ as diameter.

## CHAPTER III

## EQUATIONS OF THE FIRST DEGREE

$$
A x+B y+C z+D=0
$$

## PLANES AND straight lines

## I. The Plane

214. Every equation of the first degree represents a plane. A plane is a surface such that it contains every point on a straight line joining any two of its points.

Let $P_{1} \equiv\left(x_{1}, y_{1}, z_{1}\right)$ and $P_{2} \equiv\left(x_{2}, y_{2}, z_{2}\right)$ be any two points of the surface whose equation is

$$
A x+B y+C z+D=0, \quad . \quad . \quad[16]
$$

so that

$$
\begin{equation*}
A x_{1}+B y_{1}+C z_{1}+D=0 \tag{1}
\end{equation*}
$$

and

$$
\begin{equation*}
A x_{3}+B y_{2}+C z_{3}+D=0 \tag{2}
\end{equation*}
$$

Now, if $P_{3} \equiv\left(x_{3}, y_{3}, z_{8}\right)$ be any point on the straight line from $P_{1}$ to $P_{2}$ at a distance $d_{1}$ from $P_{1}$ and $d_{3}$ from $P_{8}$ then, by Art. 205,

$$
\begin{equation*}
x_{8}=\frac{d_{1} x_{3}+d_{2} x_{1}}{d_{1}+d_{2}}, y_{8}=\frac{d_{1} y_{3}+d_{2} y_{3}}{d_{1}+d_{3}}, \quad z_{8}=\frac{d_{1} z_{3}+d_{2} z_{1}}{d_{1}+d_{3}} \tag{3}
\end{equation*}
$$

But this point lies on the surface represented by equation [16]; for, substituting its coürdinates from (3) in equation [16], the latter becomes

$$
\frac{d_{1}}{d_{1}+d_{2}}\left(A x_{2}+B y_{2}+C z_{2}+D\right)+\frac{d_{2}}{d_{1}+d_{2}}\left(A x_{1}+B y_{1}+C_{2}+D\right)=0,
$$

which is a true equation, since each parenthesis vanishes separately by equations (1) and (2). Hence every point of the line $P_{1} P_{2}$ is on the locus of equation [16], and that locus is therefore a plane. Every algebraic equation of the first degree in three variables represents a plane.
215. Equation of a plane through three given points. The general equation of the first degree,

$$
\begin{equation*}
A x+B y+C z+D=0 \tag{1}
\end{equation*}
$$

has only three arbitrary constants, viz. the ratios of the coefficients. If three given points in the plane are

$$
P_{1} \equiv\left(x_{1}, y_{1}, z_{1}\right), \quad P_{2} \equiv\left(x_{2}, y_{2}, z_{2}\right), \text { and } P_{8} \equiv\left(x_{8}, y_{8}, z_{8}\right),
$$

then these ratios may be found from the three equations,

$$
\left.\begin{array}{l}
A x_{1}+B y_{1}+C z_{1}+D=0  \tag{2}\\
A x_{2}+B y_{2}+C z_{2}+D=0 \\
A x_{3}+B y_{8}+C z_{3}+D=0
\end{array}\right\}
$$

considered as simultaneous.
In solving equations (2) for the required ratios, two special cases may occur: (a) The value of one of the coefficients may be zero, then the ratios determined must not have that coefficient in the denominator. E.g., if $D=0$, solution should not be made for $\frac{A}{D}, \frac{B}{D}, \frac{C}{D}$, but for $\frac{A}{C^{\prime}}, \frac{B}{C^{\prime}}$ (say). (b) The equations may differ only by constant factors, then the three equations have an infinite number of solutions. This is explained by the fact that the points are on a straight line, and any plane through the line will pass also through the points.
216. The intercept equation of a plane. A plane will in general cut each coördinate axis at some definite distance
from the origin, and this distance is called the intercept of the plane on the axis. If $a, b, c$ be the intercepts on the $a$-, $y$-, and $z$-axes, respectively, of the plane whose equation is

$$
\begin{equation*}
A x+B y+C z+D=0, \tag{1}
\end{equation*}
$$

then the points $(a, 0,0),(0, b, 0),(0,0, e)$ are points of the plane, and therefore (ef. 'Art. 215)

$$
A a+D=0, \quad B b+D=0, \quad C e+D=0,
$$

i.e.,

$$
\begin{equation*}
A=-\frac{D}{a} \quad B=-\frac{D}{b} \quad C=-\frac{D}{b} \tag{2}
\end{equation*}
$$

Hence equation (1) may be written
i.e.,

$$
\begin{gather*}
\frac{D x}{a}+\frac{D y}{b}+\frac{D z}{c}-D=0, \\
\frac{x}{a}+\frac{y}{b}+\frac{z}{c}=13 \tag{1i}
\end{gather*}
$$

and this is the equation of the plane in terms of its interceptes.
217. The normal equation of a plane. A plane is wholly determined in position if the length and direction be known of a perpendicular to it from the origin; and this method of fixing a plane leads to one of the most useful forms of its equation. Let $O Q$ be the perpendicular from the origin $O$ to the plane $A B C$, let $p$ be its length, always considered as positive, and let co, $\boldsymbol{\beta}, \boldsymbol{\gamma} \boldsymbol{\gamma}$ be its direction angles. Let $P \equiv(x, y, z)$ be any point of the plane, and draw its coürdinates $O M, M M, M^{\prime} P$. Then, projecting upon $0 Q$,

$$
\text { proj. } O M M^{\prime} P=\text { proj. } O P,
$$

hence proj. $O M+$ proj. $M M^{\prime}+$ proj. $M^{\prime} P=$ proj. $O P$, that is,
$x \cos \alpha+y \cos \beta+z \cos \gamma=\boldsymbol{p}$.
This is called the normal equation of the plane.
There are two special cases to be considered :
(1) If the plane is perpendicular to a coördinate plane, c.g., to the $x y$-plane (cf. Art. 210), then $\boldsymbol{\gamma}=90^{\circ}, \cos \boldsymbol{\gamma}=0$, and equation [18] reduces to

$$
\begin{equation*}
x \cos \alpha+y \cos \beta=p . \tag{19}
\end{equation*}
$$

(2) If the given plane is parallel to one of the coördinate planes, e.g., to the $x y$-plane (cf. Art. 209); then $\alpha=\beta=90^{\circ}$, $\boldsymbol{\gamma}=0^{\circ}$, and eq. [17] reduces to

$$
\begin{equation*}
z=p \tag{20}
\end{equation*}
$$

218. Reduction of the general equation of first degree to a standard form. * Determination of the constants $a, b, c, p$, a, $\beta, \gamma$. I. Intercept form. In Art. 216 a method has been indicated for reducing the general equation

$$
\begin{equation*}
A x+B y+C z+D=0 \tag{1}
\end{equation*}
$$

to the intercept form. Since the points $(a, 0,0),(0, b, 0)$, and $(0,0, c)$ are on the plane (1), it follows that the intercepts are

$$
\begin{equation*}
a=-\frac{D}{A}, \quad b=-\frac{D}{B}, \quad c=-\frac{D}{C} . \tag{2}
\end{equation*}
$$

II. Normal form. If equation (1) and the equation

$$
\begin{equation*}
x \cos \alpha+y \cos \beta+z \cos \gamma-p=0 \tag{3}
\end{equation*}
$$

represent the same plane, then their first members can differ

[^59]only by a constant factor, m (ef. Art. 203, eqs [5]; also Art. 58);
therefore
$$
m A=\cos a_{n} \quad m B=\cos \beta, \quad m C=\cos \gamma, \quad m D=-p,
$$
but, by [4], $\quad \cos ^{2} \alpha+\cos ^{2} \beta+\cos ^{2} \gamma=1$,
hence $\quad m^{2}\left(A^{2}+B^{2}+C^{2}\right)=1$, and $m=\frac{1}{\sqrt{A^{2}+B^{2}+C^{2}}}$
Then
\[

\left.$$
\begin{array}{ll}
\cos \alpha=\frac{A}{\sqrt{A^{2}+B^{2}+C^{2}}} & \cos \beta=\frac{B}{\sqrt{A^{2}+B^{2}+C^{2}}} \\
\cos \gamma=\frac{C}{\sqrt{A^{2}+B^{2}+C^{2}}} \quad \quad p=\frac{-D}{\sqrt{A^{2}+B^{2}+C^{2}}} \tag{21}
\end{array}
$$\right\}
\]

Equation (1) written in the normal form is then

$$
\begin{align*}
& \frac{A}{\sqrt{A^{2}+B^{2}+C^{2}}} x+\frac{B}{\sqrt{A^{2}+b^{2}+C^{2}}} y \\
&+\frac{C}{\sqrt{A^{2}+b^{2}+C^{2}}} z=\frac{-D}{\sqrt{A^{2}+B^{2}+C^{2}}} \tag{5}
\end{align*}
$$

therefore, to reduce equation (1) to the normal form, it is necessary only to transpose the constant term to the second member of the equation, and then divide both members by the square root of the sum of the squares of the coefficients of the variable terms. The sign of the radical is determined by the fact (Art. 217) that $p$ is taken positive; hence, the sign of the radical is the opposite of the sign of the constant term.
219. The angle between two planes. Parallel and perpendicular planes. The angles formed by two intensecting planes are the same as the angles formed by two straight lines perpendicular to them respectively; i.e., are the same
as the angles between the respective normals from the origin to the planes. If
and

$$
\begin{align*}
& A_{1} x+B_{1} y+C_{1} z+D_{1}=0  \tag{1}\\
& A_{2} x+B_{2} y+C_{2} z+D_{2}=0 \tag{2}
\end{align*}
$$

be two planes, then the direction cosines of their normals are respectively (eqs. [21])
$\cos \alpha_{1}=\frac{A_{1}}{\sqrt{A_{1}{ }^{2}+B_{1}{ }^{2}+C_{1}{ }^{2}}}, \cos \beta_{1}=\frac{B_{1}}{\sqrt{A_{1}{ }^{2}+B_{1}{ }^{2}+C_{1}{ }^{2}}}, \cos \gamma_{1}=\frac{C_{1}}{\sqrt{A_{1}{ }^{2}+B_{1}{ }^{2}+C_{1}{ }^{2}}} ;$
$\cos \alpha_{2}=\frac{A_{2}}{\sqrt{A_{2}{ }^{2}+B_{2}{ }^{2}+C_{2}^{2}}}$, etc.,
and by equation [10], if $\theta$ be the angle between the two planes, and hence between the two normals,

$$
\begin{equation*}
\cos \theta=\frac{A_{1} A_{2}+B_{1} B_{2}+C_{1} C_{2}}{\sqrt{A_{1}^{2}+B_{1}^{2}+C_{1}^{2}} \sqrt{A_{2}^{2}+B_{2}^{2}+C_{2}^{2}}} \tag{22}
\end{equation*}
$$

There are two cases of special interest.
I. Parallel planes. If the planes (1) and (2) are parallel, their normals from the origin will have the same direction cosines, and differ only in length ; therefore, by equations [21], the equations of the planes must be such that the coefficients of the variable terms are the same in the two equations, or can be made the same by multiplying one equation by a constant. In other words, if the planes (1) and (2) are parallel, then

$$
\begin{equation*}
\frac{A_{1}}{A_{2}}=\frac{B_{1}}{B_{2}}=\frac{C_{1}}{C_{2}} ; \tag{23}
\end{equation*}
$$

and the plane $\quad A x+B y+C z+K=0$ is parallel to the plane

$$
\begin{equation*}
A x+B y+C z+D=0 \tag{4}
\end{equation*}
$$

for all values of the parameter $K$.
11. Perpendicular planes. If the planes (1) and ( - ) are perpendicular to each other, then $\cos \theta=0$, and

$$
\begin{equation*}
A_{1} A_{1}+B_{1} B_{2}+C_{1} C_{3}=0 ; \tag{24}
\end{equation*}
$$ and conversely.

220. Distance of $\varepsilon$ point from a plane. Let

$$
P_{1}=\left(x_{1}, y_{1}, x_{1}\right)
$$

be a given point, and

$$
\begin{equation*}
A x+B y+C z+D=0 \tag{1}
\end{equation*}
$$

a given plane. The perpendicular distance of $P_{1}$ from the plane is equal to the distance from the plane (1) to a parallel plane through the point, i.e., is equal to the difference in the lengths of the normals, from the origin, to these two parallel planes.

The parallel plane through $P_{1}$ has for its equation by Art. 219, equation (3),

$$
\begin{equation*}
A x+B y+C z=A x_{1}+B y_{1}+C z_{1} . \tag{2}
\end{equation*}
$$

By [21], the lengths of the normals to planes (1) and (2) are, respectively,

$$
p=\frac{-D}{\sqrt{A^{2}+B^{2}+C^{2}}}, \quad p^{\prime}=\frac{A x_{1}+B y_{1}+C C_{2}}{\sqrt{A^{2}+B^{2}+C^{2}}}
$$

therefore, if $d=p^{\prime}-p$ be the required distance,

$$
\begin{equation*}
d=\frac{A x_{1}+B y_{1}+C z_{1}+D}{\sqrt{A^{2}+B^{2}+C^{2}}} \tag{25}
\end{equation*}
$$

In formula [25], the sign of the radical is taken opposite to the sign of $D$ (Art. 218); and the sign of $d$ shows on which side of the given plane lies the given point.

## II. The Straioht Lise

221. Two equations of the first degree represent a straight line. Every equation of first degree represents a plane
(Art. 214), and two equations considered as simultaneous represent the intersections of their two loci (Art. 39). Therefore sunce two planes intersect in a straight line, the locus of the two simultaneous equations of first degree,
$A_{1} x+B_{1} y+C_{1} z+D_{1}=0, A_{2} x+B_{2} y+C_{2} z+D_{2}=0, \ldots$ (1) is a straight line. As suggested in Art. 212, it is generally more simple to represent the straight line by equations in two variables only, standard forms, to which equation (1) can always be reduced.
222. Standard forms for the equations of a straight line.
(a) The straight line through a given point in a given direction. Let $P_{1} \equiv\left(x_{1}, y_{1}, z_{1}\right)$ be a given point, and $a, \beta, \gamma$ the direation angles of a straight line through it. Let $P \equiv(x, y, z)$ be any point on the line, at a distance $d$ from $P_{1}$. Then by equation [7],

$$
\begin{equation*}
d \cos \alpha=x-x_{1}, d \cos \beta=y-y_{1}, d \cos \gamma=z-z_{1}, \tag{1}
\end{equation*}
$$

hence

$$
\begin{equation*}
\frac{x-x_{1}}{\cos \alpha}=\frac{y-y_{1}}{\cos \beta}=\frac{z-z_{1}}{\cos \gamma} ; \tag{26}
\end{equation*}
$$

which are the equations of a straight line in the first standard form, called the symmetrical equations.
(b) The straight line through two given points. Let $P_{1} \equiv$ $\left(x_{1}, y_{1}, z_{1}\right)$ and $P_{2} \equiv\left(x_{2}, y_{2}, z_{2}\right)$ be the given points. Any straight line passing through $P_{1}$ has [26] for its equations. If the line passes also through $P_{2}$, then

$$
\begin{equation*}
\frac{x_{2}-x_{1}}{\cos \alpha}=\frac{y_{3}-y_{1}}{\cos \beta}=\frac{z_{2}-z_{1}}{\cos \gamma} \tag{2}
\end{equation*}
$$

and hence from equations [26] and (2), by division to eliminate the unknown direction cosines,

$$
\begin{equation*}
\frac{x-x_{1}}{x_{2}-x_{1}}=\frac{y-y_{1}}{y_{2}-y_{1}}=\frac{z-z_{1}}{z_{2}-z_{1}} . \tag{27}
\end{equation*}
$$

These are the second stamlard forms for the eqquation of a straight line.
(c) The straight line with given traces on the codrdinate planes. One of the simplest set of planes for determining a straight line is a pair of planes through the line and perpendicular respectively to the conrdinate planes (cf. Art. 212). Then the equation of these planes will be the same as the equations of the traces of the line on the corresponding coofrdinate planes (Art. 210). Thus, if the equation of the traces of a given line upon the $z x$ - and $y z$-planes are, respectively,

$$
\left.\begin{array}{l}
x=m z+b_{1}  \tag{28}\\
y=n z+d_{3}
\end{array}\right\}
$$

then, considered as simultaneous, these are also the equastions of the given line in space.

In Fig. 155 the given traces are $A B L$ in the $\varepsilon x$-plane, and $C D N^{\prime}$ in the $y$ z-plane $P$ is any point in the given straight line, and $Q, R, S$ are the points where the line pierces the $x y$-, $y z-, 2 x$-planes, respectively. Then it is clear that in equations [28]

$$
\left.\begin{array}{l}
m=\tan \angle O A B, \quad b=O B  \tag{8}\\
n=\tan \angle O C D, \quad d=O D .
\end{array}\right\}
$$

Also, since, by equations [2s],

$$
O A=-\frac{b}{m}, A R=\frac{d m-b_{n}}{m}, O C=-\frac{d}{n}, \quad O S=\frac{l m-\lambda m}{n},
$$

therefore the points where the given line pierces the coördinate planes are

$$
\begin{equation*}
Q \equiv(b, d, 0), R \equiv\left(0, \frac{d m-b n}{m},-\frac{b}{m}\right), S \equiv\left(\frac{b n-d m}{n}, 0,-\frac{d}{n}\right) . \tag{4}
\end{equation*}
$$

223. Reduction of the general equations of a straight line to a standard form. Determination of the direction angles and traces.
I. Third standard form: traces. The traces of a straight line have the same equations as have the planes of projection of the straight line upon the coördinate planes, respectively. They may be obtained, therefore (Art. 210), by eliminating in turn each of the variables $z, y, x$ from the given equations.

This may be illustrated by a numerical example.
Given the equations

$$
\begin{equation*}
3 x+2 y+z-5=0, x+2 y-2 z=3 \tag{1}
\end{equation*}
$$

representing a straight line. Eliminating $z, y$, and $x$, successively, the equations

$$
\begin{equation*}
7 x+6 y-13=0,2 x+3 z-2=0,4 y-7 z-4=0 \ldots \tag{2}
\end{equation*}
$$

are obtained, each representing a plane through the given line and perpendicular to a coordinate plane. Therefore these equations are also the equations of the traces of the line, in the $x y$, $2 x$-, and $y z$-planes, respectively.
II. First standard form: direction angles. The method of reducing the general equations of a straight line to the first standard form, and finding its direction angles, can also be illustrated by a numerical case.

Considering still the line whose equations are (1) above, and whose traces are given by equations (2); and taking the equations of any two of its traces, e.g.,

$$
\begin{equation*}
2 x+3 z-2=0, \quad 4 y-7 z-4=0 \tag{3}
\end{equation*}
$$

these have one variahle, a in common. Equating the values of thit common variable from the two equations, givee

$$
x=\frac{-2 z+2}{8}=\frac{4 y-4}{7}
$$

which may be written, to correspond with equations [20],

$$
\begin{equation*}
\frac{z-0}{1}=\frac{x-1}{-1}=\frac{y-1}{1} \tag{4}
\end{equation*}
$$

Sow, although the denominators $1,-1$. 3 of equation (1) are not direction cosines of any line, yet, loy equations [5], they differ froms such direction cosines only by the divisor

$$
\sqrt{1+1+\frac{1 i}{}}=\frac{1}{8} \sqrt{101} .
$$

Rewriting equations ( 4 ) in the form

$$
\begin{equation*}
\frac{x-1}{\frac{-6}{\sqrt{101}}}=\frac{y-1}{\frac{7}{\sqrt{101}}}=\frac{x-0}{\frac{4}{\sqrt{101}}} \tag{5}
\end{equation*}
$$

it corresponds entirely to equations [28]. Therefore the line prasses through the point ( $1,1,0$ ), and ite direetion angles are given by the relations

$$
\cos \alpha=-\frac{6}{\sqrt{101}} \cos \beta=\frac{7}{\sqrt{101}} \quad \cos \gamma=\frac{1}{\sqrt{101}}
$$

The method given abore is evidently perfectly general.
224. The angle between two lines; between a plane and a line. If the equations of two straight lines be written in the form

$$
\begin{align*}
& \frac{x-x_{1}}{a_{1}}=\frac{y-y_{1}}{b_{1}}=\frac{z-z_{1}}{c_{1}}  \tag{1}\\
& \frac{x-x_{3}}{a_{2}}=\frac{y-y_{3}}{b_{2}}=\frac{z-z_{2}}{c_{3}} \tag{2}
\end{align*}
$$

then by Art. 223, II, their direction cosines are, respectively,

$$
\begin{gather*}
\cos a_{1}=\frac{a_{1}}{\sqrt{a_{1}^{2}+b_{1}^{2}+c_{1}^{2}}} \quad \cos a_{2}=\frac{a_{2}}{\sqrt{a_{2}^{2}+b_{2}^{2}+c_{2}^{2}}} . \\
\cos \beta_{1}=\frac{b_{1}}{\sqrt{a_{1}^{3}+b_{1}^{2}+c_{1}^{3}}}, \text { etc. .... . . } \tag{3}
\end{gather*}
$$

and therefore, by equation [10], the angle between the two lines is given by the equation

$$
\cos \theta=\frac{a_{1} a_{2}+b_{1} b_{2}+c_{1} c_{2}}{\sqrt{a_{1}^{2}+b_{1}^{2}+c_{1}^{2}} \sqrt{a_{2}^{2}+b_{2}^{2}+c_{2}^{2}}} \cdots \text { [29] }
$$

Again, the angle between the straight line

$$
\begin{equation*}
\frac{x-x_{1}}{a}=\frac{y-y_{1}}{b}=\frac{z-z_{1}}{c} \tag{4}
\end{equation*}
$$

and the plane

$$
\begin{equation*}
A x+B y+C z+D=0 \tag{5}
\end{equation*}
$$

is the complement of the angle between the line (3) and the perpendicular to the plane (4) from the origin. Therefore, by equations [10] and [21], and Art. 223, II, the required angle is given by the equation

$$
\begin{equation*}
\sin \theta=\frac{a A+b B+c C}{\sqrt{a^{2}+b^{2}+c^{2}} \sqrt{A^{2}+B^{2}+C^{2}}} . \tag{30}
\end{equation*}
$$

Conditions for perpendicularity and parallelism precisely like those of Art. 219 may be obtained from equations [29] and [30].

## EXAMPLES ON CHAPTER III

1. Find the equations of a line through the points $(1,2,3)$ and $(3,2,1)$.
2. Find the equation of a plane through three points $(1,2,3)$, $(3,2,1)$, and (2, 3, 1).
3. Write the equations of the straight line through the point ( $1,2,3$ ), and having its direction cosines proportional to $\sqrt{3}, 1,2 \sqrt{3}$.
4. What are the traces of the line of Ex. 1 upon the coördinate planes? Where does the line pierce those planes?
5. Find the equations of a straight line through the point $(1,2,3)$ and perpendicular to the plane $x+2 y+3 z=6$.

Reduce to the intercept and normal forms, and determine which octant each plane cuts :
6. $2 x-3 y-z=7$;
7. $5 y+2 z-1=x$.
8. Rocluce the equations of the fime

$$
2 x-3 y-z=7, \quad 6 y+2 z-1=z
$$

to the symmetrical form, and determine its dinection ousises.
9. Find the angle betweon the planes

$$
2 x-3 y-z=7, \quad 5 y+2 z-1=z
$$

10. Find the angle between the line

$$
\text { and the plane } \begin{array}{r}
x+y+2 z=0,2 x-y-2 x-1=0 \\
3 x+6 z-5 y+1=0 .
\end{array}
$$

12. Write the equation of a plane parallel to the plame

$$
2 z-y+7 z-5=0
$$

and parsing through the point $(0,0,0)$; through the point $(-1,1,-1)$.
12. Write the equation of a plane perpendicular to the plane

$$
3 x+5 y-z+6=0
$$

and prassing through the two points $(3,1,2)$ and ( $0,-2,-4$ ).
13. Find the distances of the prointe $(5,-2,3)$ and $(3,3,1)$ from the plane $2 x+5 y-z-9=0$. Are they on the same side of the plane ?
14. At what angle does the plane $a x+b y+c z+d=0$ eut each coordio nate plane? Each coordinate axis?
15. Find the equation of a plane through the groint $(1,1,1)$ and perpendicular to each of the planes

$$
2 x-3 y+7 z=1, \quad z-y-2 z=2
$$

16. Write the equation of a plane whose distance from the point $(0,2,1)$ is 3 , and which is perpendicular to the radius vector of the point ( $2,-1,-1$ ).
17. Write the equation of a straight line through the point $(5,2,6)$ which is parallel to the line

$$
2 z-3 z+y-2=0, \quad x+y+z+1=0
$$

18. Find the traces on the coordinate plames of the line

$$
2 x-8 z+y-2=0, \quad x+y+z+1=a
$$

19. Prove that the planes

$$
\begin{gathered}
2 x-8 y+z+1=0 \\
5 x+z-1=0 \\
23 x+3 y+4 z-6=0
\end{gathered}
$$

have one line in common.
20. What is the equation of the plane determined by the line

$$
2 x-3 z+y-2=0, \quad x+y+z+1=0
$$

and the point $(5,2,6)$ ?
21. Show analytically that the locus of a point equidistant from three given points is a straight line perpendicular to the plane determined by those three points.
22. Derive equation [17] directly from a figure, without using equation [16].

## CHAPTER IV

## EQUATIONS OF THE SECOND DEGREE

## QUADRIC SURFACES

225. The locus of an equation of second degree. The mont general algebraic equation of second degrve in three variables may be written

$$
\begin{align*}
A x^{2} & +B y^{2}+C z^{2}+2 F y z+2 G x z+2 M x y+2 I x+2 M y \\
& +2 N z+K=0 . \tag{81}
\end{align*}
$$

Any surface which is the locus of an equation of second degree is called a quadric surface, and is of particular interest because of its close connection with and analogy to the conie sections. In fact, every plane section of a quadric is a conic, as may be easily shown as follows.

By Art. 207, any plane may be chosen as a coördinate plane. and the transformation of coordinates to the new axes will leave the degree of equation [31] unchanged; i.e., the new equation of the locus will still be of the form [31], though with different values for the coefficients. To find the nature of any plane section, choose the given plane as (any) the ryplane of reference, and transform to the new axes; the new equation will be of form ( 1 ). Then let $z=0$. The equation of the section of the quadrie is

$$
\begin{equation*}
A x^{3}+B y^{2}+2 H x y+2 L x+2 M y+K=0 ; \ldots \tag{1}
\end{equation*}
$$

and this, by Art. 175, represents a conic.

Moreover, the trace of the surface on any parallel plane, as $z=a$, is given by the equation

$$
\begin{align*}
A x^{2}+B y^{2} & +2 H x y+2(L+a G) x+2(M+a F) y \\
& +\left(C a^{2}+2 N a+K\right)=0 \tag{2}
\end{align*}
$$

Now, by Arts. 177, 181, the loci of equations (1) and (2) are conics of the same species, and with semi-axes proportional ; therefore their eccentricities are equal, and the curves are similar. Hence, all parallel plane sections of a quadric are similar conics.
226. Species of quadrics. Simplified equation of second degree. As will be seen in the following sections, quadric surfaces may be conveniently classed under four species. For, although different plane sections of any surface will in general be conics of different species, still the general form of the surface may be characterized most strikingly by those plane sections which are ellipses, hyperbolas, parabolas, or straight lines. These species are called, respectively, ellipsoids, hyperboloids, paraboloids, and cones; and each species has special varieties, depending upon the nature of a second system of plane sections. To study these species it will be well to simplify the general equation of second degree as much as possible by a suitable transformation of coördinates.*

A transformation of coördinates changing to a new rectangular system having the same origin as the old, by equations [14], will transform the given equation of second degree to

$$
\begin{align*}
A^{\prime} x^{2}+B^{\prime} y^{2} & +C^{\prime} z^{2}+2 F^{\prime} y z+2 G^{\prime} x z+2 H^{\prime} x y+\ddots L^{\prime} x \\
& +2 M^{\prime} y+2 N^{\prime} z+K=0 \tag{1}
\end{align*}
$$

where $A^{\prime}, B, \cdots N^{\prime}$ are functions of the nine direction angles
${ }_{1}, \pi_{2}, \cdots$ of the new axes, which are limited by the six inde. prodent equations noted in Art. 207. These angles, therefore. may be so chosen that three adilitional eonditions shall be fulfilled; hence, so that the cocflicients $F^{\prime \prime}, G^{\prime}$, and $I^{\prime}$ shall vanish. Then the new equation of the quadrie will be

$$
\begin{equation*}
A^{\prime} x^{2}+B^{\prime} y^{2}+C^{\prime \prime} z^{2}+2 I^{\prime} x+2 M^{\prime} y+2 N^{\prime} z+K=0 . \tag{2}
\end{equation*}
$$

Now a second transformation may be mate to a parallel system of axes through a new origin ( $h, k, j)$, by equations [13], giving for the new equation
$A^{\prime} A^{2}+B^{\prime} y^{3}+C z^{2}+2 L^{\prime \prime} x+2 M^{\prime \prime} y+2 N^{\prime \prime} z+K^{\prime}=0$, (B)
in which $L^{\prime \prime}, M^{\prime \prime}, \boldsymbol{N}^{\prime \prime \prime}$, and $\boldsymbol{K}^{\prime \prime}$ are functions of the courdinates $h, k$, and $j$; and these coordinates may be chosen so that $L^{\prime \prime}, M^{\prime \prime}$, and $N^{\prime \prime}$ will vanish, giving for the simplified form of the equation of the given quadric.

$$
\begin{equation*}
A^{\prime} x^{3}+B^{\prime} y^{2}+C^{\prime \prime} z^{3}+K^{\prime \prime}=0 . \tag{4}
\end{equation*}
$$

It may happen, however, that the choice given above for the direction angles $a_{1}, a_{2}, \cdots$, of the new axes is such that the coefficient of one more term of second degree, as $C^{\prime \prime}$, will also vanish ; then equation (4) would reduce to

$$
\begin{equation*}
A^{\prime} x^{2}+B^{\prime} y^{2}+K^{\prime}=0 \tag{5}
\end{equation*}
$$

and the surface is a cylinder (Art. 210). Again, if also $\boldsymbol{L}^{\prime \prime}$. $M^{\prime}, N^{\prime \prime \prime}$ are not independent, and the values of $h, k, j$ as gisen above are therefore indeterminate, then $h, k, j$ may be chosen so that, for example, $L^{\prime \prime}, M^{\prime \prime}$, and $\boldsymbol{K}^{\prime}$ shall ranish ; and the equation of the qquadric becomes

$$
\begin{equation*}
A^{\prime} x^{2}+B^{\prime} y^{2}+2 N^{\prime \prime} z=0 \tag{6}
\end{equation*}
$$

[^60]The two forms of the quadric, not already discussed,* have therefore for their equations, when simplified (dropping the accents),
and

$$
\begin{equation*}
A x^{2}+B y^{2}+C z^{2}+K=0 \tag{32}
\end{equation*}
$$

$$
A x^{2}+B y^{2}+2 N z=0
$$

$$
[38]
$$

A center of a surface is a point such that it bisects every chord of the surface which passes through it. It is clear that the locus of equation [32] is a central quadric, while the locus of equation [33] is non-central (cf. Art. 178).
227. Standard forms of the equation of a quadric. For convenience of discussion, the intercepts of the locus of equation [32] on the coördinate axes may be represented by $a, b, c$, respectively, so that

$$
\begin{equation*}
a^{2}=-\frac{K}{A}, \quad l^{2}=-\frac{K}{B}, \quad c^{2}=-\frac{K}{C} \tag{1}
\end{equation*}
$$

Then, since $A, B, C$, and $K$ cannot be all of the same sign, there will be three types of equation [32], according to the signs of $A, B, C$, and $K$; viz.:

$$
\begin{align*}
& \frac{x^{2}}{a_{0}^{2}}+\frac{y^{2}}{b^{2}}+\frac{z^{2}}{c^{2}}=1  \tag{2}\\
& \frac{x^{2}}{a^{2}}+\frac{y^{2}}{b^{2}}-\frac{z^{2}}{c^{2}}=1  \tag{3}\\
& \frac{x^{2}}{a^{2}}-\frac{y^{2}}{b^{2}}-\frac{z^{3}}{c^{2}}=1 \tag{4}
\end{align*}
$$

Similarly, equation [33] may be written for convenience in the typical forms

$$
\begin{align*}
& \frac{x^{2}}{a^{2}}+\frac{y^{2}}{b^{2}}=z  \tag{5}\\
& \frac{x^{2}}{a^{2}}-\frac{y^{2}}{b^{2}}=z \tag{6}
\end{align*}
$$

[^61]wherein, however, a and b aro no longer intercoptes as in (2). (8), and (4).

Again, if the equation [32] has its constant term zero, it may be written in two typical forms,

$$
\begin{align*}
& \frac{x^{3}}{a^{2}}+\frac{y^{3}}{b^{3}}+\frac{a^{2}}{c^{2}}=0 . \quad . \quad .  \tag{i}\\
& \frac{a^{3}}{a^{2}}+\frac{y^{3}}{b^{3}}-\frac{a^{2}}{c^{2}}=0 . \quad . \quad . \quad . \tag{8}
\end{align*}
$$

These seven equations are atandard forms of the equation n! second degree, and will be discussed in turn.
228. The ellipsoid: equation $\frac{x^{2}}{a^{2}}+\frac{y^{2}}{b^{2}}+\frac{z^{2}}{c^{2}}=1$. From the equation

$$
\begin{equation*}
\frac{x^{3}}{a^{2}}+\frac{y^{2}}{b^{2}}+\frac{a^{8}}{c^{2}}=1 \tag{34}
\end{equation*}
$$

the following properties of its locus may he derived :
(1) The traces on each coobrdinate plane are ellipses, having

the semi-axes $a$ and $b$ in the $x y$-plane, $b$ and $c$ in the $y z$ plane, and $c$ and $a$ in the $z x$-plane.
(2) The traces on planes parallel to any coördinate plane are similar ellipses (Art. 225).
(3) The equation may be written

$$
\frac{y^{2}}{\frac{b^{2}\left(a^{2}-x^{2}\right)}{a^{2}}}+\frac{z^{2}}{c^{2}\left(a^{2}-x^{2}\right)} \frac{a^{2}}{}=1 ;
$$

hence for a plane section parallel to the $y z$-plane, the semiaxes are real if the value of $x$ lies between $-a$ and $+a$, imaginary if beyond those limits, and zero if $x= \pm a$. Moreover, the length of the axes diminish continuously from the values $b$ and $c$, respectively, when $x=0$ to the value zero, when $x= \pm a$.
Similarly for sections parallel to either of the other coördinate planes.
(4) The surface is symmetrical with respect to each coordinate plane.

This quadric surface, the locus of equation [34], is called an ellipsoid. It may be conceived as generated by a variable ellipse, which has its vertices upon, and moves always perpendicular to, two fixed ellipses, which in turn are perpendicular to each other and have one axis in common.

From this definition equation [34] can be easily derived. Let $C R A$ and $A S B$ be fixed ellipses perpendicular to each other, and having the semi-axis OA in common,
 and the second axes $O C$ and $O B$, respectively; and let $S P R$ be the variable ellipse, with semi-axes $M S$ and MR. If $O A, O B, O C$ be taken as the $x, y, z$ axes, respectively; and $P$ be any point on the moving ellipse, with coördinates OM, $M M^{\prime}, M^{\prime} P$, then (by Art. 112),
$W I^{3}+\frac{M M^{2}}{M E^{2}}=1$
$\frac{W G^{2}}{U C^{3}} \cdot \frac{\bar{U} M^{3}}{U A^{4}}=1$
$\frac{\omega s^{3}}{\omega B^{3}}-\frac{\overline{D I^{2}}}{U A^{3}}=1$,
i.e. $\frac{2^{2}}{M \mu^{2}}+\frac{y^{9}}{M / s^{2}}=1$,
$\frac{\pi x^{2}}{c^{3}}+\frac{x^{3}}{a^{3}}=1$,
(i) $\frac{\sqrt{75}}{v^{3}}+\frac{x^{2}}{d^{3}}=1$. (5)

By equatlons (2) and (3),

$$
M_{h^{2}}=c^{3}\left(1-\frac{x^{2}}{a^{3}}\right), \quad M_{3}^{2}=b^{3}\left(1-\frac{x^{2}}{a^{3}}\right)
$$

Suhmetitution in (1) gives $\frac{x^{2}}{a^{2}}+\frac{y^{2}}{b^{2}}+\frac{z^{2}}{e^{2}}=1$.
Every algebraic equation of the form

$$
A x^{2}+B y^{2}+C z^{2}-K=0
$$

represents an ellipsifid. If two of the coefficients of the variable terms are equal it is an ellypsoid of revolution, either an oblate or prolate spheroid; and if the three eoreflicients of the variable terms are equal, it is a sphere (cf. Art. 213, eqs. (10). (11), and (8)).
229. The un-parted hyperboloid: equation $\frac{x^{2}}{a^{2}}+\frac{y^{2}}{b^{2}}-\frac{z^{2}}{c^{2}}=1$. From the equation

$$
\begin{equation*}
\frac{x^{2}}{a^{2}}+\frac{y^{2}}{b^{2}}-\frac{z^{2}}{c^{2}}=1 \tag{35}
\end{equation*}
$$

the following progerties of its locus may hee derived:
(1) The trace on the $r y$-plane is an ellipse, with semi-axes a and 8 ; while the traces on the $y z$ - and $2 x$-planes are hyperbolas, having the semi-axes $b$ and $c, c$ and $a$, respectively, and the conjugate axes along the $z$-axis.
(2) The traces on planes parallel to any coordinate plane are similar conics, ellipses or hyperbolas respectively (Art. 225).
(3) The traces on the planes $x=a, x=-a, y=b, y=-b$ are in each case a pair of intersecting straignt lines.

(4) The equation may be written

$$
\begin{align*}
& \frac{x^{2}}{\frac{a^{2}\left(c^{2}+z^{2}\right)}{c^{2}}}+\frac{y^{2}}{\frac{b^{2}\left(c^{2}+z^{2}\right)}{c^{2}}}=1, \quad . \quad \text {. . (1) } \\
& \frac{y^{2}}{\frac{b^{2}\left(a^{2}-x^{2}\right)}{a^{2}}}-\frac{z^{2}}{\frac{c^{2}\left(a^{2}-x^{2}\right)}{a^{2}}}=1 . \quad . \quad . \quad \text {. (2) } \tag{2}
\end{align*}
$$

or

From equation (1) it appears that the trace on the $x y$-plane is the smallest of the system of ellipses parallel to that plane, and that the sections increase continuously and indefinitely as $z$ increases from 0 to $\pm \infty$.

From equation (2) it appears that the transverse axis of the hyperbolas parallel to the $y z$-plane is parallel to the $y$-axis. Similarly, for the $x z$-sections the transverse axis is parallel to the $x$-axis.
(5) The surface is symmetrical with respect to cach cur ordinate plane.

This quadrie surface, whose equation is [35], is called an un-parted hyperboloid, or an hyperboloid of one sheet. Is may be conceived as generated by a rariable ellipse, which has its vertioes upon and moves always perpendicular to two fixed hyperbolas, which in turn are perpendieular to each other, and have a common conjugate axis. Its equation can be readily obtained from this defintion."

Every equation of the form $A x^{3}+B y^{3}-C z^{3}-K=0$ represents an un-parted byperboloid. If the two positive coeflicients are equal, i.e., if $a=b$, the quadric is the simple lyyerboloid of revolution (Art. 213, eq. (12)).
230. The bi-parted hyperboloid: equation $\frac{x^{2}}{a^{2}}-\frac{y^{2}}{b^{2}}-\frac{s^{2}}{s^{3}}=1$. From the equation

$$
\begin{equation*}
\frac{x^{3}}{a^{3}}-\frac{y^{2}}{b^{2}}-\frac{z^{2}}{c^{2}}=1 \tag{36}
\end{equation*}
$$

the following properties of its lowus may be derived:

- C\%. An. ges.
(1) The traces on the $x y$-and $z x$-planes are hyperbolas, with semi-axes $a$ and $b, c$ and $a$, respectively, and with the transverse axis along the $x$-axis, while the traces on the planes parallel to the $y z$-plane are imaginary if $x$ lies between $a$ and $-a$, real ellipses if $x$ is beyond those limits, and points if $x= \pm a$.
(2) The traces on planes parallel to any coördinate plane are similar (Art. 225).
(3) The elliptical sections parallel to the $y z$-plane increaso continuously and indefinitely as $x$ varies from $+\boldsymbol{a}$ to $+\infty$, or from $-a$ to $-\infty$.
(4) The surface is symmetrical with respect to each coördinate plane.

This quadric surface, whose equation is [36], is called a bi-parted hyperboloid, or hyperboloid of two sheets. It may le conceived as generated by a variable ellipse which has its vertices upon, and moves always perpendicular to, two fixed hyperbolas which in turn are perpendicular to each other, and have a common transverse axis. This definition leads readily to the equation [36].

Every equation of the form $A x^{2}-B y^{2}-C z^{2}-K=0$ represents a bi-parted hyperboloid. If the coefficients of the two negative variable terms are equal, i.e., if $b=c$, the sur face is the double hyperboloid of revolution (cf. Art. 213, eq. (13)).
231. The paraboloids: equation $\frac{x^{2}}{a^{2}} \pm \frac{v^{2}}{b^{2}}=z_{0}$ A disoussion of the equation

$$
\begin{equation*}
\frac{x^{2}}{a^{2}}+\frac{y^{2}}{b^{2}}=a \tag{37}
\end{equation*}
$$

similar to that of the preceding articles shows that its locus
is as represented in Fig. 160, symmetrical with respect to the $y z$ - and $a x$-plane, but not with respect to the ry-plane. This quadric is the elliptic paraboloid, and may be conecired as being generated by a variable parabola which has its vertex upon, and moves

Fin 100 always perpendicular to, a fixed parabola, the axes of the two parabolas being parallel and lying in the same direction. This detinition leads directly to equation [37].*

Every equation of the form $A s^{3}+B y^{2}-2 N z=0$ reprosents an elliptic paraboloid. If the two positive coefficients are equal, the quadric is a paraboloid of revolution (cf. Art. 218, eq. (14)).

Similarly, the equation $\frac{a^{2}}{a^{2}}-\frac{y^{2}}{b^{3}}=a \quad . \quad . \quad$.

Fio 161
has for its loous a surface as represented in Fig. 161. This quadric is the hyperbolic paraboloid, and may be conceived as generated by a variable parabola which has its vertex upon and moves always perpendicular to a fixed parabola, the axes of the two parabolas being parallel, but lying in opposite directions. Equation [38] may be derived at once from this definition.*

Every equation of the form $A x^{2}-B y^{2}-2 N z=0$ repre sents an hyperbolic paraboloid.
232. The cone: equation $\frac{x^{2}}{a^{2}}+\frac{y^{2}}{b^{2}}-\frac{z^{2}}{c^{2}}=0$. The equation
 $\frac{x^{2}}{a^{2}}+\frac{y^{2}}{b^{2}}+\frac{z^{2}}{c^{2}}=0$ evidently is satisfied by the coördinates of only one real point, viz. the origin. No further discussion of this equation is necessary. But the equation

$$
\begin{equation*}
\frac{x^{2}}{a^{2}}+\frac{y^{2}}{b^{2}}-\frac{z^{2}}{c^{2}}=0 \tag{39}
\end{equation*}
$$

has a locus of importance, having the following properties.
(1) The origin is a point of the locus.
(2) The trace on the $x y$ plane is a point. The traces on planes parallel to the $x y$-plane are similar ellipses, whose semi-axes increase continuously and indefinitely as $z$ increases from 0 to $\pm \infty$.
(3) The trace on each of the other coördinate planes is a pair of straight lines which intersect at the origin.

[^62](4) Tha surface is symmetrical with respect to ench eoûdinate plane, hence also with respect to the origin.
(5) The straight line through the origin and any othor point of the loens lies whelly in the teens.
This quadric surface is called a cone, and the origin is ite vertex. It may be conceived as generated by a straight lino which moves along a fixed ellipse as directrix, and passes through a fixed point in a straight line which is perpen dicular to the plane of the ellipse at its center.
Every equation of the form $A x^{3}+B y^{3}-C s^{3}=0$ repre. sents a cone. If the two positive coefficients are equal, it is a cone of revolution, or circular cone (ef. Art. 213, eq. (9)).

The reasoning of Art. 225, applied to the special equation of the form [31] which represents a cone, gives an analytio proof of the fact that every plane seetion of a cone is a second degree curve (cf. Art. 48; Appentix, Note D).
233. The hyperboloid and its asymptotic cone. The hyperboloid

$$
x^{2}-\frac{y^{2}}{b^{2}}-z^{2}=1
$$

and the cone

$$
\frac{x^{2}}{a^{2}}-\frac{y^{2}}{b^{3}}-\frac{z^{2}}{c^{3}}=0
$$

are closely related. It is clear that, since the equations differ only in the constant terms, the surfaces can have no finite points in common; while as the values of $y$ and $z$ are inereased indefinitely, the correspotaling values for $x$ from the two equations le-

Pro. 163
come relatively nearer. In fact, the hyperboloid may be said to be tangent to the cone at infinity, and bears to the cone a relation entirely analogous to that between the hyperbola and its asymptotes. In the same way, the cone $\frac{x^{2}}{a^{2}}+\frac{y^{2}}{l^{2}}-\frac{z^{2}}{c^{2}}=0$ is asymptotic to the hyperboloid $\frac{x^{3}}{a^{2}}+\frac{y^{2}}{b^{2}}-\frac{z^{2}}{c^{2}}=1$.

## EXAMPLES ON CHAPTER IV

1. Derive the equation [35] directly from the definition of Art. $22 \Omega$.
2. Derive the equation [36] directly from the definition of $\mathbf{A r t} .230$.
3. Derive the equations [37], [38] directly from the definitions of Art. 231.
4. Derive the equation [39] directly from the definition of Art. 232 .
5. Show analytically that the intersection of two spheres is a circle.
6. Find the equation of the tangent plane to the sphere $(x-u)^{2}$ $+(y-u)^{2}+(z-c)^{2}=r^{2}$, at any point of the sphere.
7. Show that the equation $A x_{1} x+B y_{1} y+C z_{1} z+K=0$ represents a plane tangent to the quadric, $A x^{2}+B y^{2}+C z^{2}+K=0$, at the point ( $x_{1}, y_{1}, z_{1}$ ) on the quadric.
8. Find the equation of the cone with origin as vertex and the ellipse $\frac{x^{2}}{9}+\frac{y^{2}}{4}=1$ in the plane $z=-2$, as directrix.
9. Find the equation of a sphere having the line from $P_{1} \equiv\left(x_{1}, y_{1}, z_{1}\right)$ to $P_{2} \equiv\left(x_{2}, y_{2}, z_{2}\right)$ as a diameter.
10. Show that a sphere is determined by four points in space.

Write the equation of the quadric whose directing curves bave the equations:
11. $\frac{x^{2}}{2}+\frac{y^{2}}{3}=1$, and $\frac{y^{2}}{8}+\frac{z^{2}}{9}=1$.
12. $\frac{x^{2}}{9}-\frac{y^{2}}{4}=1$, and $\frac{x^{2}}{9}-\frac{z^{3}}{16}=1$.
13. $\frac{x^{2}}{9}-\frac{y^{2}}{4}=1$, and $\frac{y^{2}}{4}-\frac{z^{2}}{16}=1$
14. $z^{2}=16 x$, and $y^{2}=9 x$.
15. $x^{2}-4 y=0$, and $z^{2}+3 y=0$.

## APPENDIX

## NOTE A

Historical sketch. Amalytie Geometry, in the form in which it is now knewn, was invented by Rend Deseartes ( $1: 596-1650$ ) and fins problished tyy him in 1637, in the third section of a treatise on unisersal secience entitled "Diseours de la méthod pour bien conduire na ralson ef chereher lo verite dans ta aciencos." Ite made the fuvention whine attempting to solve a certain problem, proposed by Pappus, the moat important case of which is: to find the locus of a polnt such that the product of the perpendiculars drawn from it upon m given atraight lines shatl bear a constant ratio to the product of the perpendtenlars drawn from it upon $n$ other given straight lines. By pure geomeiry this problem had already been solved for the apecial cases when $m=1$ and $n=1$ or 2. Pappus had aiso aserted, but without proof, that when $m=n=2$, then the locus of this point is a connc. In his effort to prove this facs Descartes introdnced his system of courdinates and found the equation of the locus to be of the second degree, thus proving that it is a conie.

Analytie geometry does not consist merely (as is sometimes loenely gaid) in the application of algehra to geometry; that had been done by Archimedes and many others, and had beeome the ustual mecthod of procedure in the works of mathetuaticians of the aixteenth century. But in all these earlier applications a special set of axes were required for each individual curve. The great advance made by Dessartes was that he saw that a puint could twe comptetely determined it its divtanees, say s and $y$, from two fixed lines, drawn at right angles to each other, in the plane, were given : and that theugh an equation $f(x, y)=0$ is indeterminate and can be satisfied loy an infinite number of values of $x$ and $g . y \mathrm{ct}$ these values of $x$ and $y$ determine the cotirlinates of a number of points which form a curve of which the equation $f(x, y)=0$ exprosess some grometric property, i.e., a property true for every point of the curve. Moreorer, he saw that this method emables one to refor all the curves that may be under investigation to the same set of axes; and that in
order to investigate the properties of a curve it is sufficient to select any characteristie geometric property, as a definition, and to express it as an equation by means of the (current) coorrdinates of any point on the carve; i.e., to translate the definition into the language of analytic geometry - the equation so obtained contains implicitly every property of the curve, and any particular property can be deduced from it by ordinary algebra.

While the earlier geometry is an admirable instrument for intellectual training, and while it frequently affords an elegant demoustration of some proposition the truth of which is already known, it requires a special procedure for each individual problem; on the other hand, analytic geometry lays down a few simple rules by which any property can be at once proved. It is incomparably more potent than the geometry of the ancients for all purposes of research.

## NOTE B

Construction of any conic, given directrix, focus, and eccentricity. Let $D^{\prime} D$ be the directrix, $F$ the focus, and $e$ the eccentricity of a conic (ef. Part I, Art. 48), to plot the curve.

Construction: Draw $Z F X$ perpendicular to $D^{\prime} D$, and $Z W$ so that, if $\alpha=\angle X \% W$, tan $a=e$. Now draw $F R$ perpendicular to $Z F$, cutting $Z W$ at $R$; then $R$ is a point of the conic ; it is the end of the latus rectum.

Bisect the right angles at $F$ by $F H_{1}$ and $F H_{2}$ intersecting $Z W$ in $H_{1}$ and $H_{2}$ and draw $\Pi_{1} 4$ and $H_{2} A^{\prime}$ perpendicular to $Z X$; then $A$ and $A^{\prime}$ are points on the curve; they are the vertices of the conic.

Again, from any peint $G$ betwem $\Pi_{1}$ and $\Pi_{2}$ on $Z W$, drsw MG jero pendicular to Z.X. cutting it at M: and Irom $F$ an a center wilh $M G$ as radius describe an are cutting $M G$ at $P$. Then $P$ is a point of the curve.

Proef: for the point $R, \frac{F R}{Z F}=\tan a=0$;

$$
\begin{aligned}
& \text { for the point } A, \frac{A F}{Z A}=\frac{A H_{3}}{Z A}=\tan e=s ; \quad\left[\angle A F H_{1}=4:\right] \\
& \text { for the point } P, \frac{F P}{Z M}=\frac{M g}{Z M}=\tan a=e ;
\end{aligned}
$$

hence the points $R, A_{y}$ and $P$ are such that their distances from the directrix and from the foens are in the ratio e; and esach is therefore. according to the definition given in Art. 4s, a point of the conte. By ploting various points $P$ (and the symmetrical points $P^{P}$ ) and contueting them by a smowth curve, the conle may lee phatted to any repuireat degree of accuracy.

If $a<45^{5}$, then tana $<1$, i.e., $e<1$, and the conic is an ellipme; if $a=45$, the eomie is a parabola; and if $a>45$, the cotice is an hyperlaola (cf. Part I, Art. 48).

## NOTE C

The special cases of the conics. The locus of the mecond degree curve has been seen to have three species, aceording as $e<1, e=1$, or e> $=1$.

If $e=0$, then, since $b$ is defined by the equation $b^{b}=a^{d}\left(1-e^{0}\right), b=a$, and the curve is an ellipre with equal axes, i.e., it is a circle: in this case aloo, the dimectrix is at infinity and the focus at the center. for the equastion of the directrix is $x=\frac{g}{e}$, and the distance from the center to the focus is ae (ef. Part I, Arta. 110, 116).

Again, suppose the focus $F$ to be on the directrix. Then, if $P$ ' is any point of the locus, and $L P$ perpendicular to $F D$,
and

$$
\begin{gather*}
F P=e \cdot L P  \tag{1}\\
\sin \angle P F L=\frac{L P}{F P}=\frac{1}{e} ;
\end{gather*}
$$

hence the angle PFL is constant, with two supplementary values for a given value of $e$.

The locus consists therefore of two straight lines intersecting at $F$, and equation (2) shows that:
if $e>1$, the lines are real and different;
if $e=1$, the lines are real and coincident;
and if $e<1$, the lines are imaginary, and the real part of the locus consists of the point $F$.

Suppose now the directrix, with the focus upon it, to be at infinity; then, if $e>1$, the locus is a pair of parallel lines.

These results agree with those already summarized in Art. 182.

## NOTE D

Sections of a cone made by a plane. The following proposition is due to Hamilton, Quételet, and others (see Taylor's Ancient and Modern Geometry of Conics, p. 204).

If a right circular cone is cut by a plane, and two spheres are inscribed in the cone and tangent to this plane, then the section of the cone made by the plane is a second degree curve (cf. Part I, Arts. 48, 175), of which the foci are the points of contact of the spheres and the plane, and the directrices are the lines in which this plane intersects the planes of the circles of contact of the spheres and the cone.

Construction: Let $O-V W$ be a right circular cone cut by the plane IIK in the section RPSQ, $P$ being any point of the section. Inseribe two spheres, $C-A B F$ and $C^{\prime}-A^{\prime} B^{\prime} F^{\prime}$, whose circles of contact with the cone are $A E B$ and $A^{\prime} E^{\prime} B^{\prime}$, respectively, and which are tangent to the plane $H K$ in the points $F$ and $F$. Through $P$ draw the element $O P$ of the cone, cutting the circles of contact in the points $E$ and $E^{\prime}$. Also pass a plane $M N$ through the circle $A E B$, and therefore perpendicular to the axis $O C C^{\prime}$ of the cone; it will intersect the plane $H K$ in a straight
line GDf, which is perpeudicular to the straght line $F^{P} P$. Draw $P^{\prime} L$ perpendioular to GDL

Then PL makes a constant angle $\theta(\equiv \angle F D . A)$ with the plane $M / N$ [since $P I$, is parallel to $F F$ ], and, if $p$ represents the distance from the point $P$ to the plane M.V,

$$
\begin{equation*}
P=P L \sin Q \quad . \quad . \quad . \tag{1}
\end{equation*}
$$

Also PE, being an element of the cone, makes a constant angle as with the plane $M A N$, and

$$
\begin{equation*}
p=P E \sin c \tag{ㄹ}
\end{equation*}
$$

Again, aince tangents from an external point to a sphero aro equal,

$$
\begin{equation*}
P E=P F \tag{3}
\end{equation*}
$$

Hence, from equations (1), (2), and (3)

$$
\begin{equation*}
\frac{P F}{P L}=\frac{\sin \theta}{\sin u}=e, \text { a constant, } \tag{4}
\end{equation*}
$$

i.e., the ratio $P F: P$, for every point $P$ of the section $S P R Q$, is constant. and (Part 1, Arts. 48, 175) the section is a second degree curve, with a focus at $F$, directrix $G D L$, and eccentricity $\frac{\sin \theta}{\sin \theta}$.

Similarly, $l^{*}$ is the other focus, and the line of intersection of the planes $H K$ and $A^{\prime} E^{\prime} B^{\prime}$ is the other directrix of the conic $S P R Q$; hence the theorem is established.

Moreover, the plaue $V W$, being perpendicular to the axis of the cone, and $O V W$, being a section made by a plane passing through the axis, $a=\angle O I W$, and is constant for a given cone, while $\theta=\angle O S R$, and varies only with the plane $H K$.

Hence the eccentricity varies with the inclination of the plane IIK, and there are the three following cases:

$$
\begin{aligned}
& \text { if } \theta<a \text {, then } e<1 \text {, and the section is an ellipse; } \\
& \text { if } \theta=a \text {, then } e=1 \text {, and the section is a parabola; } \\
& \text { if } \theta>a \text {, then } e>1 \text {, and the section is an hyperbola. }
\end{aligned}
$$

Again, if the cutting plane $H K$ passes through the vertex $O$ of the cone, then the focus $F$ is on the directrix $G D L$, and the section will be either a pair of straight lines or a point:
if $\theta<\alpha$, the section is a point, the vertex $O$ of the cone.
if $\theta=\alpha$, the section is a pair of coincident straight lines, an element of the cone;
if $\theta>a$, the section is a pair of intersecting straight lines, two elements through the vertex (cf. Note C).
It is, of course, evident that for every elliptic section of the focal spheres both lie in the same nappe of the cone, and touch the plane of the section ( $H K^{\prime}$ ) on opposite sides; while for every hyperbolic section these focal spheres lie one in each nappe of the cone, and both on the same side of the plane of the section.

In the above proof, for the sake of simplicity, a right circular cone was employed; it is easy to sinow (see Salmon's Conic Sections, p. 329) that every section of a second degree cone (right or oblique) by a plane is a second degree curve.
 ing case of ans ellipme (et. Sote K).

## NOTB E

Parabola the limit of an ellipse, ${ }^{*}$ of of an hyperbola. If a vertes and the correspoming foeus of an ellipme remain fixed in poestion whille the center moves furthor and further away, the major asis lewotmug infinitely long, then the form of the ellipme approarines mare and mase nearly to that of a purabola having the same vertex and foeve.

This is easily shown as follows:
The empation of the ellipme referred to its major axis and the tangent at its lefthand vertex, as coürdinate axes, is (Part 1, Art. 112)

$$
\begin{equation*}
\frac{(x-a)^{3}}{a^{2}}+\frac{y^{3}}{b^{1}}=1 \tag{1}
\end{equation*}
$$

which may be written in the form

$$
\begin{equation*}
y^{4}=\frac{2 b^{3}}{a} x-\frac{8^{3}}{a^{2}}= \tag{2}
\end{equation*}
$$

If now the fixed distance $O F$ be represented by $p$, then
whence

$$
P=O F=O C-F C=a-\sqrt{a^{2}-b^{3}},
$$

$$
\text { therefure } \quad \frac{2 b^{2}}{a}=4 p-\frac{2 p^{2}}{a} \text {, and } \frac{b^{2}}{a^{3}}=\frac{2 p}{a}-\frac{p^{2}}{a^{4}}
$$

[^63]Substituting these values in equation (2) it becomes

$$
\begin{equation*}
y^{2}=\left(4 p-\frac{2 p^{2}}{a}\right) x-\left(\frac{2 p}{a}-\frac{p^{2}}{a^{2}}\right) x^{2} \tag{3}
\end{equation*}
$$

and the limit of this equation as $a$ approaches $\infty, p$ remaining constant, is

$$
\begin{equation*}
y^{2}=4 p x ; \tag{4}
\end{equation*}
$$

which is the equation of a parabola, and the proposition is proved.
In the same way it may be shown that the parabola is the limit to which an hyperbola approaches when its center moves away to infinity, a vertex and the corresponding focus remaining fixed in position (cf. also Note D).

## NOTE $F$

Confocal conics. -Two conics having the same foci, $F_{1}$ and $F_{2}$, are called confocal conics. Since the transverse axis of a conic passes through the foci and its conjugate axis is perpendicular to, and bisects, the line joining the foci, therefore confocal conics are also coaxial,* i.e., they have their axes in the same lines. If the equation of any one of such a system of conics is

$$
\begin{equation*}
\frac{x^{2}}{a^{2}}+\frac{y^{2}}{b^{2}}=1 \tag{1}
\end{equation*}
$$

and if $\lambda$ is an arbitrary parameter, then the equation

$$
\begin{equation*}
\frac{x^{2}}{a^{2}+\lambda}+\frac{y^{2}}{b^{2}+\lambda}=1 \tag{2}
\end{equation*}
$$

will represent any conic of the system. For, $a$ and $b$ being constant, and $a>b$, equation (2) represents ellipses for all values of $\lambda$ between $\infty$ and $-b^{2}$, hyperbolas for all values of $\lambda$ between $-b^{2}$ and $-a^{2}$, and imaginary loci when $\lambda<-a^{2}$; moreover, the distance from the center $O$ to either focus for each of these curves is

$$
\sqrt{\left(a^{2}+\lambda\right)-\left(b^{2}+\lambda\right)}
$$

which equals $\sqrt{a^{2}-b^{2}}$, and is therefore constant.
The individual curves of the system represented by equation (3) are obtained by giving particular values to $\lambda$, each value of $\lambda$ determining one and but one conic. If any one of these conics is chosen as the

[^64]fundamental conic, and represented by equation (1), then each of the other conics of the system may be designated by ite appropriate ralue of $\lambda$.

Through any assigned point, $P_{1} \equiv\left(x_{1}, y_{1}\right)$ of the plane, there panees one ellipme and one hyperbola of the syatem represented by equation (2). For suhatituting the coordinates $x_{1}$ and $y_{1}$ of $P_{1}$ in equation (2), it gives the quadratic equatiou

$$
\begin{equation*}
\frac{x_{1}^{2}}{a^{2}+\lambda}+\frac{y_{1}^{3}}{b^{2}+\lambda}=1 \tag{3}
\end{equation*}
$$

for the determination of $\lambda$. Equation (3) gives two values of $\lambda$, hence two conics of this confocal system pass through $\boldsymbol{P}_{1}$. That one of these is an ellipse and the other an hyperbola is shown as follows: the guadratic function in $\boldsymbol{\lambda}$

$$
\frac{x_{1}^{8}}{a^{2}+\lambda}+\frac{y_{1}^{2}}{b^{3}+\lambda}-1
$$

is negative when $\lambda=+\infty$, and, as $\lambda$ decreases from $+\infty$ to $-\infty$, this function becomes positive just before $\lambda=\alpha b$, negative again just aftes $\lambda \approx-b^{2}$, and positise again fust before $\lambda=-a^{3}$; hence, of the two roots of equation (3), oue lies between - $b^{4}$ and ax, and the other between $-a^{2}$ and $-b^{2}$; and therefore of the two confocal conies which pase through $P_{1}$, one is an ellipse and the other an hyyertola. Moreover, the two confocal comies which pass through any given print, as $P_{1}=\left(x_{1}, y_{1}\right)$. of the plane intersect at right angles. This is easily seen geometrically thus: comect $P_{1}$ with the fori $F_{1}$ and $F_{2}$, then the tangent $P_{1} T_{3}$ to the
hyperbola through $P_{1}$ hisects the interior angle between $F_{1} P_{1}$ and $F_{2} P_{1}$, while the tangent $P_{1} T_{3}$ to the ellipse through this same point bisects the external angle formed by these two lines (cf. Part I, Arts. 148, 163); these tangents are therefore at right angles, hence (cf. Part I, Art. 100) the conics intersect at right angles.

This fact could also have been readily proved analytically by comparing the equations of the two tangents.

Remark 1. It is easily seen that as $\lambda$ approaches - $b^{2}$ from the positive side, the ellipses represented by equation (2) grow more and more flat (because the length of the semi-minor axis $\sqrt{b^{2}+\lambda}$ approaches 0 ), approaching, as a limit, the segment $F_{1} F_{2}$ of the indefinite straight line through the foci. On the other hand, if $\lambda$ approaches - $b^{2}$ from below, then the hyperbolas grow more and more flat, approaching, as a limit, the other two parts of this line. Again, if $\lambda$ approaches $-a^{2}$ from above, the hyperbolas approach the $y$-axis as a limit.

Remark 2. Since through every point of a plane there passes one ellipse and one hyperbola of the confocal system represented by equation (2), and but one of each, therefore the two values of $\lambda$ which determine these two curves may be regarded as the coordinates of this point ; they are known as the elliptic coordinates of the point. If the rectangular coördinates of a point are known, the elliptic coördinates are easily found by means of equation (2).
E.g., let $P_{1} \equiv\left(x_{1}, y_{1}\right)$ be the point in question, then the elliptic coördinates of $P_{1}$ are the two values of $\lambda$, which are the roots of equation (3). So, too, if the elliptic coördinates are given, the Cartesian coördinates can be found.

Remark 3. The above observations concerning confocal conics are easily extended to confocal quadrics, i.e., to quadric surfaces whose principal sections are confocal conics. They are represented by the equation

$$
\frac{x^{2}}{a^{2}+\lambda}+\frac{y^{2}}{b^{2}+\lambda}+\frac{z^{2}}{c^{2}+\lambda}=1
$$

## ANSWERS

## Page 0. Art. 7.

4. Yes
5. ㄷes.
6. Yem, if e in prositive ; yea.
7. $x=a$.
8. Yes; yes; yea.

## Page 10. Art 9.

1. (2), (3), (4), and (5) are identities 8. Roven tumghasy.
2. $z=-\frac{3+m}{4(2+m)} i \frac{1}{4(2+m)} \sqrt{-3!m m^{2}-n d m-}$ an ; rovis are equal if

3. (1) imagnary; (2) imaginary ; (3) real and uneyual.
4. (1) $m=2$ or -48 ; (2) $m=-1$ 古 $\pm 1$ 枋 $\sqrt{ }-19$; (3) $m=3$ or -5 ;

13. $3 x+2 y+4=0 ; 8 x^{2}+2 x y+4 x+9=0$.

## Pages 296, 297. Art. 176.

1. Center $\equiv(0, \sqrt{2}) ; \quad$ foci $\equiv( \pm \sqrt{6}, \quad \sqrt{2} \pm \sqrt{6}) ;$ axes: $y-x=\sqrt{2}$, $y+x=\sqrt{ } 2 ;$ directrices : $x+y=\frac{2 \pm 3 \sqrt{3}}{\sqrt{2}}$.

$$
\left(\frac{\sqrt{2}}{2} \frac{1}{2}\right) \text {; and the bacm mertum to } 4 \sqrt{ } \text { B. }
$$

 the new $y$-axis, the memi-axes beling $\sqrt{ }$ ? and $\}$.
2. Parabola ; $\theta=40^{\circ}$; the vertex (relerred to old axes), is the polat ( $b, 1$ ); $p=\frac{3 \sqrt{2}}{4}$

## Page 308. Examples on Chapter XII.

1. Ilypertola; $\theta=45^{\circ}$, conerlinates of center (whal axer) are: (H) $-11) ; a^{8}=414,88=4 j^{2}$.
2. Parabolas $\theta=4 \bar{v}^{\circ}$; the new equantion is:

$$
\left(y-\frac{3}{4 \sqrt{2}}\right)^{2} x-\frac{\sqrt{2}}{3}\left(x-\frac{25 \sqrt{2}}{10}\right)
$$

3. Filipere; $\theta=0$; center (ald axemb) $\left(\frac{1}{3}, \frac{-1}{4}\right) ; a^{2}=31 . b^{3}=13$; socl on new y-axis.
4. Two straight lines : $3 x+y=5$, and $3 y-x=2$.
5. Two paralle lines: $2 x-y=0$, and $2 x-y+2 a=0$.
6. A "point ellipme," or two imaginary meraight linees through the origin.
7. Circle ; center (old axes) $\equiv \mid-14, D: r^{3}=11$.
8. Hyperbola; center (old axem) $\mathrm{E}(-3,-71, \theta=22]^{\prime} ; d^{3}=b^{3}=\frac{2}{\sqrt{2}}$.
9. Two atraight lines : $2 x+y+1=0$, and $3 x-y=0$.
10. Two straight lines : $x-y=0$, and $y+3=0$.
11. The hyperbola $48 x^{2}-11 x y-17 y^{2}-120 x+24 y+81=0$
12. The parabola $10 x^{3}+72 x y+81 y^{2}-23 x-355 y+144=0$.
13. The circle $(x-6)^{2}+(y+2)^{2}=26$.

## Page 341. Examples on Chapter 1. Part II

$2 \cos a=\frac{1}{\sqrt{14}}, \cos \beta=\frac{2}{\sqrt{14}}, \cos y=\frac{3}{\sqrt{14}}$
2. $2000=\mathrm{M}$ 湤,
4. $\left(4,30^{\circ}, 30^{\prime}\right)$.
8. $\{1 \sqrt{8}, 1 \sqrt{2}, 1 \sqrt{2}$ ).

9. $p_{1}=5 \sqrt{3}, \quad \cos a_{1}=-\frac{7}{5 \sqrt{3}}, \quad \cos \beta_{1}=\frac{1}{5 \sqrt{3}}, \quad \cos \gamma_{1}=\frac{1}{\sqrt{3}} ;$
$\rho_{2}=\sqrt{6}, \cos a_{2}=\frac{1}{\sqrt{6}}, \cos \beta_{2}=-\frac{1}{\sqrt{6}}, \cos \gamma_{2}=-\frac{2}{\sqrt{6}} ;$
$\rho_{3}=\sqrt{a^{2}+b}, \quad \cos a_{3}=\frac{a}{\rho_{s}}, \cos \beta_{3}=0, \quad \cos \gamma_{8}=\frac{b}{\rho_{8}}$.
10. $(2,2,2)$.
11. $a=\beta=\gamma=\cos ^{-1} \frac{1}{\sqrt{3}}$.
12. $\cos ^{2} \beta=\frac{\sqrt{3}}{4}-1$

## Page 352. Examples on Chapter II, Part II.

1. Two coincident planes parallel to the $y z$-plane and at the distance +3 from it.
2. A plane parallel to the $y z$-plane and at the distance -2 from it.
3. Two coincident planes parallel to the $z$-axis and intersecting the $x y$-plane in the line $x-y+1=0$.
4. Two planes intersecting in the z-axis, and intersecting the $x y$-plane in the lines $y=\frac{-b \pm \sqrt{b^{2}-4 a c}}{2 c} x$.
5. Hyperbolic cylinder with generators paraliel to the $x$-axis.
6. A parabolic cylinder with generators parallel to the $x$-axis.
7. A circle whose plane is parallel to the $x z$-plane and whose equation is $3 x^{2}+3 x^{2}=17$.
8. A pair of lines respectively parallel to $y= \pm x$.
9. The projection of this curve upon the $x z$-plane is the hyperbola $3 x^{2}-z^{2}+5=0$, and its projection on the $y z$-plane is the ellipse $3 y^{2}+4 z^{2}=32$.
10. For $z=5$, the point $(0,0,5)$; for $z=-5$ it is a circle parallel to the $x y$-plane, and whose equation is $9 x^{2}+9 y^{2}=100$.
11. Solved like No. 9 . 12. $x^{2}+y^{2}=25 ; x^{2}+4 z^{2}=25 ; y^{2}+4 z^{2}=25$.
12. Solved like No. 12.
13. $y^{2}+z^{2}+5 x=3$.
14. $(y-3)^{2}=25\left(x^{2}+z^{2}\right)$; vertex $\equiv(0,3,0)$.
15. $\frac{x^{2}+y^{2}}{3}+\frac{z^{2}}{2}=1$.
16. $\frac{x^{2}+y^{2}}{7}+\frac{z^{2}}{9}=1$.
17. $x^{4}\left(y^{2}+z^{2}\right)=1$.
18. $16 x^{2}-9 y^{2}-9 z^{2}=1$.
19. $x^{2}+y^{2}+z^{2}=6 x$.

## Page 364. Examples on Chapter III, Part II.

1. $x+z=4, y=2$.
2. $x+y+z=6$.
3. $\frac{x-1}{\sqrt{3}}=\frac{y-2}{1}=\frac{z-3}{2 \sqrt{3}}$
4. $y=2$ (on $x y$-plane), $y=2$ (on $y z$-plane), $x+z=4$ (on $x z$-plane); it plerces the $x y$-plane at $(4,2,0)$, the $y z$-plane at $(0,2,4)$, and is parallel $t$ the $x$-plane.
B. $\frac{x-1}{1}=\frac{y-2}{2}=\frac{z-3}{3}$.
a. $\frac{\pi}{i}+\frac{y}{-i}+\frac{z}{-7}=1 ; \frac{22}{\sqrt{14}}-\frac{3 y}{\sqrt{14}}-\frac{8}{\sqrt{14}}=\frac{7}{\sqrt{16}}$
\%. $\frac{z}{-1}+\frac{y}{i}+\frac{z}{1}=1 ;=\frac{z}{\sqrt{30}}+\frac{5 y}{\sqrt{3} w}+\frac{3 z}{\sqrt{20}}=\frac{1}{\sqrt{30}}$
5. $\frac{x-6}{1}=\frac{y}{8}=\frac{8-3}{-7}, \frac{1}{\sqrt{69}}, \frac{3}{\sqrt{60}}, \frac{-i}{\sqrt{60}} \quad$ 2. coe $P=\frac{-19}{2 \sqrt{106}}$
$10 \quad \sin \theta=\frac{-16}{6 \sqrt{14}} \quad$ 11. $2 z-y+7 z=0 ; 2 z-y+7 z+10=0$.
6. $11 x-7 y-8 z=28$.
7. $\frac{-8}{\sqrt{20}} \frac{81}{\sqrt{200}} ; 20$.
8. $\operatorname{con}^{-1}\left(\frac{a}{\sqrt{a^{3}+b^{2}+c^{3}}}\right)$ for the ys-plams, $\cos ^{-1}\left(\frac{b}{\sqrt{a^{3}+b^{2}+C}}\right)$ tur the $z:-$ plane, and $\cos ^{-1}\left(\frac{c}{\sqrt{a^{2}+b^{2}+c^{3}}}\right)$ for the $x y-\beta$ pane, $\sin ^{-1}\left(\frac{a}{\sqrt{a^{2}+b^{2}+r^{3}}}\right)$. $\sin ^{-3}\left(\frac{b}{\sqrt{c^{3}+b^{3}+c^{2}}}\right)$, and $\sin ^{-1}\left(\frac{c}{\sqrt{\alpha^{2}+b^{2}+c^{3}}}\right)$ reapectuvely for the $2 \operatorname{asin}$, the $y$-axin, and the $z$-axis.
9. $18 x+11 y+8=25$.
10. $2 z-y-s=-3(1 \pm \sqrt{ } 8)$.
11. $\frac{x-6}{4}=\frac{y-2}{-6}=\frac{a-6}{1}$
12. $y+6 z+4=0, z-4 z=3,6 z+4 y+1=0$.
13. $18 x+11 y-17 x=10$.

## Page 380. Examples on Chapter IV. Part II.

6. $\left(z_{1}-a\right)(z-a)+\left(y_{1}-b\right)(y-b)+\left(s_{1}-c\right)(z-b)=r^{2}$ is the tangens Dlane at $\left(x_{1}, y_{1}, z_{1}\right)$.
7. $4 x^{2}+9 y^{4}=9 x^{2}$.
8. $\left(z-\frac{z_{1}+x_{2}}{2}\right)^{2}+\left(y-\frac{y_{1}+y_{3}}{2}\right)^{2}+\left(z-\frac{z_{1}+z_{2}}{2}\right)^{3}$

$$
=\frac{\left(z_{1}-x_{3}\right)^{2}+\left(y_{1}-y_{1}\right)^{2}+\left(y_{1}-s_{i}\right)^{2}}{4}
$$

11. $\frac{x^{2}}{2}+\frac{x^{2}}{3}+\frac{z^{2}}{9}=1$.
12. $\frac{x^{3}}{9}-\frac{x^{3}}{4}-\frac{x^{2}}{16}=1$.
13. Impoesible.
14. $16 y^{2}+9 z^{2}=141 z$.
15. $3 x^{2}-4 x^{3}=12 y$.

## Text-Books on Surveying

## RAYMOND'S PLANE SURVEYING

By William G. Raymond, C.E., Member American Society<br>of Civil Engineers ; Professor of Geodesy, Road Engineering, and Topographical Drawing in Rensselaer Polytechnic Institute<br>$\$ 3.00$

This work has been prepared as a manual for the study and practice of surveying. The long experience of the author as a teacher in a leading technical school and as a practicing engineer has enabled him to make the subject clear and comprehensible for the student and young practitioner. It is in every respect a book of modern methods, logical in its arrangement, concise in its statements, and definite in its directions. In addition to the matter usual to a full treatment of Land, Topographical, Hydrographical, and Mine Surveying, particular attention is given to system in office work, to labor-saving devices, the planimeter, slide rule, diagrams, etc., to courdinate methods, and to clearing up the practical diffculties encountered by the young surveyor. An appendix gives a large number of original problems and illustrative examples.

## Other Text-Books on Surveying

DAVIES'S ELEMENTS OF SURVEYING (Van Amringe) ..... $\$ 1.75$
ROBINSON'S SURVEYING AND NAVIGATION (Root) ..... 1.60
SCHUYLER'S SURVEYING AND NAVIGATION ..... 1.20

Copies will be sent, prepaid, to any address on reccipt of the price.

# Biology and Zoölogy 

## DODGE'S INTRODUCTION TO ELEMENTARY PRACTICAL BIOLOGY

> A Laboratory Guide for High School and College Students. By Crarles Wrigur Donge, M.S., Professor of Biology in the University of Rochester . . . . . . $\$ 1.80$

This is a manual for laboratory work rather than a text-book of instruction. It is intended to develop in the student the power of independent investigation and to teach him to observe correctly, to draw proper conclusions from the facts observed, to express in writing or by means of drawings the results obtained. The work consists essentially of a series of questions and experiments on the structure and physiology of common animals and plants typical of their kind-questions which can be answered only by actual investigation or by experiment. Directions are given for the collection of specimens, for their preservation, and for preparing them for examination; also for performing simple physiological experiments.

## ORTON'S COMPARATIVE ZOÖLOGY, STRUCTURAL AND SYSTEMATIC

By James Orton, A.M., Ph.D., late Professor of Natural History in Vassar College. New Edition revised by Charles Wrigitr Dodge, M.S., Professor of Biology in the University of Rochester $\$ 1.80$
This work is designed primarily as a manual of instruction for use in higher schools and colleges. It aims to present clearly the latest established facts and principles of the science. Its distinctive character consists in the treatment of the whole animal kingdom as a unit and in the comparative study of the development and variations of the different species, their organs, functions, etc. The book has been thoroughly revised in the light of the most recent phases of the science, and adapted to the laboratory as well as to the literary method of teaching.

Copies of either of the above books will be sent, prcpaid, to any address on receipl of the price.

## Standard Text-Books in Physics

## ROWLAND AND AMESS ELEMENTS OF PHYSICS

By Hener A. Kowland, Ph. D., LL. D., and Jougres S. Aska, Ph.D., Professors of Plyysics in Johns Hopkins University.
Cloth, $12 \mathrm{mo}, 275$ pages . . . Prico, $\$ 100$
This is designed to meet the reguirements of bigth schoots and normal schools, and is simple line logival and direct, being dirided into two parts-the first trating of the theory of the subject, and the second comtainng suggestions to teachers.

## AMES'S THEORY OF PHYSICS

## By Joseph S. Aurs, Ph. D.

Cloth, 8vo, 531 pages.
Price. $\$ 1.60$
In this test-book, for adranced classes, the aim has been to furnish a concíse and logical statement of the fundamental experiments on which the science of Pbysies is based, and to correlate these experiments with modern theories and methods.

## ames and bliss's manual of experiments in phrsics

By Josepa S. Ames, Ph, D. Professor of Pbysics, and IThlaam J. A. Buss, Ph. D., Associate in Physics, in Johns Hopkins University.
Cloth, 8vo, 360 pages . . . . . . Price. $\$ 1.80$
A course of laboratory instruction for advanced classes, embodying the most improved methods of demonstration from a modern standpoint, with numerous questions and suggestions as to the value and bearing of the experiments

# Text-Books in Geology 

By JAMES D. DANA, LL.D.<br>Late Professor of Geology and Mineralogy in Yale University.

## DANA'S GEOLOGICAL STORY BRIEFLY TOLD $\$ 1.15$

A new and revised edition of this popular text-book for beginners in the study, and for the general reader. The book has been entirely rewritten, and improved by the addition of many new illustrations and interesting descriptions of the latest phases and discoveries of the science. In contents and dress it is an attractive volume, well suited for its use.

DANA'S REVISED TEXT-BOOK OF GEOLOGY
$\$ 1.40$
Fifth Edition, Revised and Enlarged. Edited by William North Rice, Ph.D., LL.D., Professor of Geology in Wesleyan University. This is the standard text-book in geology for high school and elementary college work. While the general and distinctive features of the former work have been preserved, the book has been thoroughly revised, enlarged, and improved. As now published, it combines the results of the life experience and observation of its distinguished author with the latest discoveries and researches in the science.

DANA'S MANUAL OF GEOLOGY . . . . . . $\$ 5.00$
Fourth Revised Edition. This great work is a complete thesaurus of the principles, methods, and details of the science of geology in its varied branches, including the formation and metamorphism of rocks, physiography, orogeny, and epeirogeny, biologic evolution, and paleontology. It is not only a text-book for the college student but a handbook for the professional geologist. The book was first issued in 1862 , a second edition was published in 1874, and a third in 1880. Later investigations and developments in the science, especially in the geology of North America, led to the last revision of the work, which was most thorough and complete. This last revision, making the work substantially a new book, was performed almost exclusively by Dr. Dana himself, and may justly be regarded as the crowning work of his life.

Copies of anny of Dana's Geologies will be sent, prepaid, to any address on receipt of the price.

# BOWNE'S THEISM 

BY BORDEN P. BOWNE<br>Prolester of Philosogity in Ihoston University

## FOR COLLEGES AND THEOLOGICAL BCHOOLS

PRICE. 51.75

THIS BOOK is a revision and extension of the author's previous work, "Phillosophy of Thelsm" In the present volume the arguments, espectally from eplatemology and metaphysles, recelve fuller treatment. The werk has been largely rewritten, and about half as much addmtional new matter has been Included.

The author, however, still adheres to his original plan of giving the essentlal arguments, so that the reader may discern thelf true nature and be enabled to estrmate thetr rattonat value. He does this from the conviction that the important thing in theistic discussion is not to make bulky collections of striking facts and eloquent fllustrations, nor to produce learmed catalogues of theistle writers and thelr works. but to elear up the logical principles which underile the subject. From this point of view the work might rightly be called the " Logic of Theism."

Special attention is given to the fact that atheistle argument is properly no argument at all. but a set of Mliusions which inevitably spring up on the plane of sense-thought, and aequire plausiblifty with the uncritical. The author seckis to lay tare the root of these fallacies and to expose them in their baselessness. In addition, the practical and vital nature of the theistle argument is emphasized, and it is shown to be not merely nor mainly a matter of sytlogistic and acaderile inference, but one of life, action, and hlstory.

Copies uners, prepaid, an receipe of prioe

## a descriptive catalogue of hich SCHOOL AND COLLEGE TEXT-BOOKS

WE issue a complete descriptive catalogue of our text-books for secondary schools and higher institutions, illustrated with authors' portraits.

For the convenience of teachers, separate sections are published, devoted to the newest and best books in the following branches of study:

ENGLISH
MATHEMATICS
MISTORY AND POLITICAL SCIENCE SCIENCE

MODERN LANGUAGES
ANCIENT LANGUAGES
PHILOSOPHY AND EDUCATION

If you are interested in any of these branches, we shall be very glad to send you on request the catalogue sections which you may wish to see. Address the nearest office of the Company.

# A New Astronomy 

BY

DAVID P. TODD, M.A., Ph.D.<br>Professor of Astronomy and Director of the Observatory, Amherst College.

Cloth, $12 \mathrm{mo}, 480$ pages. Illustrated - Price, $\$ 1.30$

This book is designed for classes pursuing the study in High Schools, Academies, and Colleges. The author's long experience as a director in astronomical observaturies and in teaching the subject has given him unusual qualifications and advantages for preparing an ideal text-book.

The noteworthy feature which distinguishes this from other text-books on Astronomy is the practical way in which the subjects treated are enforced by laboratory experiments and methods. In this the author follows the principle that Astronomy is preëminently a science of observation and should be so taught.

By placing more importance on the physical than on the mathematical facts of Astronomy the author has made every page of the book deeply interesting to the student and the general reader. The treatment of the planets and other heavenly bodies and of the law of universal gravitation is unusually full, clear, and illuminative. The marvelous discoveries of Astronomy in recent years, and the latest advances in methods of teaching the science, are all represented.

The illustrations are an important feature of the book. Many of them are so ingeniously devised that they explain at a glance what pages of mere description could not make clear.

Copies of Todd's New Astronomy will be sent, prepaid, to any address on reccipt of the price by the Publishers:

## S\&M <br> A <br> 47

[^0]:    - All these kinds of numbens will be met and better illustrated in succeeding chapters of this book. E.g, see Art, bis, Nute.

[^1]:    - Thesign $\doteq$ is read "approaches as a limit." It was introduced by the • Late Professor Oliver of Cornell Cniversity.

[^2]:    - Hereafter, anless otherwime statesl, projection will be understood to mean orthugomal prujection.

[^3]:    - These minus signs are written high merely to indicate that they are signs of quality and not of operation.

[^4]:    - This kind of symmetry is known as cyclic (or circular) symmetry. If the numbers 1,2 , and 3 be arranged thus $0_{2}^{3}$, then the subscripts in the first term (in [4a] say) begin with 1 and follow the arrow heads around the circle (i.e. their order is $1,2,3$ ), those of the second term begin with 2 and follow the arrow heads (their order is 2, 3, 1), and those of the third term begin with 3 and follow the arrow heads.

[^5]:    - If $s$ and $y$ are reganled as the coonlimates of the joims of futerac chan, the sulsecriptes may be omitted here.

[^6]:    - If equations whose second members are not zero are multiplied together, member by member, the resulting equation is not satisfied by any points of the loci of the given equations except those in which they intersect each other; the new equation therefore represents a locus through the points of intersection of the loci of the given equations.

[^7]:    - Thas proof shows clearly that if the comorlinates of any point os the seraight line through $P_{1}$ and $P_{g}$ are substituted for an and $y$ in equation (1) the fint member will be equal to ze:mo ; if the coordinates of any pumt leflue this line are so substituted the first member will be orgative; and if che consdirates of any print above this line are sos substituted the first memiker will tee positive. This line may then be reganded as the boundary whids separates that part of the plane for which $3 y-x-3$ is negatise from the part for which this function is prositive. Bemanse of this fact that side of this tine an whirh $P_{3}$ lies may be called the negatime side, and the other the prosition atile.
    t See aleo Art. 89.

[^8]:    - The positive side of this line is that side on which the origin lies (cf. foot-note, Art. 43).
    t See also Art. 98.
    I Except in elementary geometry, the word "circle" is employed by most writers on mathematies to mean "circumference of a circle." It will be so used in this book.

[^9]:    tax. an. asom. - 8

[^10]:    - This property enables one to construct any number of points lying on the parabola, thus: with $F$ as center, and any radius not less than $\frac{1}{2} O F$, describe a circle, then draw a line parallel to $O Y$ and at a distance from it equal to the chosen radius; the points in which this line cuts the circle are points on the parabola. Other points can be located in the same way. See also Note B, Appendix.
    + Equation (4) enables one $w$ construct any number of points on the

[^11]:    - For most of the suggeations in this article, and in the examples that follow it, the authors are intebted to Mr. J. S. Shearer of the Department of Physies of Cornell C'niversity.

[^12]:    - Taken by perminaion from Lambert's Analytic Geometry.

[^13]:    - Throughout this book the more important formulas are printed in boldfaced type; they should be committed to memory by the learner.

[^14]:    - See alou Eix. 6 below.

[^15]:    - If either $A$ or 13 , say $A$, is zero, then the equation may be written in the furm : $y=-\frac{C}{I 3}$, which is the equation of a straight line parallel to the a-axia. and at the distance $-\frac{\mathrm{C}}{B}$ from it [cf. Art. 33, (2)].

[^16]:    - This conclusion may also be drawn thus: clear equation (6) of fractions, transjose all the terms to the first member, and multiply by $\frac{1}{2} \sin \omega$;

[^17]:    the reaulting equation awerts [see Ar, 20, (1)] that the area of the triangle formeed by the points $P_{1}, P_{v}$, and $P_{3}$, is zero; $f$ fe, these three points lie on a straight line ; but they are any three points on the locus of $A x+B y+C=0$, bence that leeves is a straight line.

    - These reductions constitute a second proof of the theorem of $A$ rL $35^{\circ}$.
    if $\mathrm{C}=0$, the the represented by (1) goes through the origin, and the symmetric form of the equation fo inapplicatile (Art son): but, in that case. the atove relurtion alse fails, since it is not permissible to divide the membeve of an equation by zero.

[^18]:    - If $B=0$, the line represented by equation (1) is parallel to the $y$-axis. and the slope form of the equation is inapplicable (Art. 56); but, in that case, the above reduction also fails.

[^19]:    

[^20]:    - It must not be forgoteen thas this conclusion is drawn only for lines that are not perpendicular to the z-axis; because if the lines are perpendicular to the $x$-axis then equations (1) and (2) are inapplicable (ef. Art. 6B).

[^21]:    - The angles a and $\beta$ are the dirrefion angles of the line O.N, and their cosines are the direction cominna of that line.

[^22]:    - Observe the symmetry here ; cf. foot-note, Art. 29.

[^23]:    - These formulas can also be read directly from Fig. in by finst projectIng $O I /$ and then the broken line $O M^{\prime} P \cdot M$ upen a line perpendieular to $O Y$; and afterwards projecting MP and also the bruken line MOM'P upon a perpendicular to 0.5 . The resulus being equated in each case, and divided by siaus, give [20].

[^24]:    - For illustration, see Art. 84.

[^25]:    - Thus erguatiou is sometianes spoken of as the magicul eynathon of the tangent

[^26]:    - The difference between equations (2) and (5) consists in this: no matter where the poluts $\left(x_{1}, y_{1}\right)$ and $\left(x_{0}, y_{2}\right)$ may be, equation (2) represents the straight line passing through them ; bus equation (b) is the equation of the line through these points only when thry are on the circte $x^{3}+y^{2}=r$. In other werls, equation (2) is the equation of the line pasaing througth any twa puints whiatever, whille equation ( $\theta$ ) is the equation of the line posing thitough ang two points on the circumfereace of the circle.

[^27]:    - Equations (11) and (12) are, of course, but different forms of the equation of the same tangent as that roprosented by equations [30].

[^28]:    - If the circle is given by the equation $A x^{2}+A y^{2}+2 G x+2 F y+C=0$, it must first be divided by $A$ before applying this theorem.
    $\dagger$ The expression $x_{1}^{2}+y_{1}^{2}+2 G x_{1}+2 F y_{1}+C$ is called the povoer of the point $P_{1} \equiv\left(x_{1}, y_{1}\right)$ with regard to the circle $x^{2}+y^{2}+2 G x+2 F y+C=0$.

[^29]:    - These conclusions may almos be stated thus: if $P_{3}$ is outside of the circle, equation (t) gives two real and distinct values for m ; correspending the these there are two real and distinet tangents ; if $P_{1}$ is on the cirele, the two values of $m$ are real lout coincident, and there are two mal but combitent tanzonts ; if $P_{1}$ is inside of the circle, the two values of me are imagmary, and the two corresponding tangents are therefore aloo imagiuary.

[^30]:    - The axis of a curve should the carvfully diviligguished from an axis of coirdimites; though they uften are culscident lises in the figures to bo studied.

[^31]:    - If $a=8$ (i.e., if $e=0$ ) this equation representa a circle. The ellipmes, thetu, incluiles the circle as a npecial case. In other worls: a circle is an -ilipwe whoee cocentricity is zero.

[^32]:    - The student should ebserve that b is the semi-minomaxis and not nes. cosily the denominatur of $y^{2}$ in the standant formin of the equatioss of the eillfer - [44]. [45], or [46]; he should also observe thas the foci are always on the omajor aris.

[^33]:    - That sign (+or - ) which makes the fraction positive is to be used.

[^34]:    - Since the equation of the normal [51] is so readily deduced, in every particular case, from that of the tangent, and since the latter is so easily remembered, it is not recommended that equation [51] be memorized.

[^35]:    - For oniy one print, via: : $I^{\prime \prime} \equiv(2 p, 0)$, are all the rools of eyuation (2) equal.

[^36]:    - Equation (5) might have been obtained at once as a special form of eyuation [34], Art. 129, by giving appropriate values to the coeficienta $\boldsymbol{A}_{1}, \boldsymbol{B}$ $F, 17$, and $C$ there used.

[^37]:    - The eccentric angle of any given point $P$ on an ellipee is meadily constrmeted this: produce the ondinate MP to meet the major auxiluary circle in $Q$; the augle $A O Q$ is the eccentric angle of the point $P$.

[^38]:    -The equations [60] are of great service in studying the ellipse by the methods of the differential calculus.

[^39]:    - This definition implies that the distance between a curve and ita aspmptate becomes infinitely small. MeMabom a Snyder, Differential Calculux, Chap. XIV.

[^40]:    - The forms of this article are useful in the differenual calculus

[^41]:    тая. Аж. огом. - 19

[^42]:     \% and $y^{\prime}$ in equation (2), may be obtained by sutuctuting s and $\beta$ for $z$ and of the firat nuember of equation (1).

[^43]:    тAX. Ax. ©EOM, - 80

[^44]:    - This curve was invented, by a Greek mathematician mamed Diocles, for the purpose of molving the celebrated probletn of the linsertion of twe mean proportionals between two givenstruight lines. The solution of this problem Carries with it the solution of the even more fatmons Delan problem of cons:ructing a cube whose volume shall be equal to two times the volume of a given culve. For, let a the the edge of the given culve; canstruct the two tuean proportionals $x$ and $y$ between a and $2 a ;$ then $a: x: 0 x: y: 0: 8: 2$, whence $x^{4}=2 \cdot a^{1}$, i.e., $x$ is the elge of the required cube. If $a=1$, then $z=\sqrt[V]{2}$, hence the insertion of two mean propertionals enables one to construct a line equal to the cube root of 2. The cissond may alos te employest to construct a line equal to the cube root of any given number (see Kietn, Flomentargoometrie, $\mathrm{S}, 35$, or the Eingliah tramalation by l'rofemons Beman and Smich).

    It is net pasitively known just when Itheiles lived; is is very probable, however, that it was in the last half of the second eentury w.c.

[^45]:    - Dincles named his curve "cissoid" (from a Greek word meaning "ivy," because of its resemblance to a vine climbing upwards. The name "cissoid" is sometimes, though rarely, applied to other curves which are generated as stated in the definition given above, except that some other basic curve is employed instead of a circle. For other, but equivalent, definitions of the cissoid see Note 3, below.

[^46]:    - To inmert fwo mean proportionala between two given lizes by meane of the círovid. See Cantar, Gewhichte der Machematik, IM. I., S. 328.

[^47]:    - The conchoid was invented by a Greek mathematician named Nicomedes. probably in the second century b.c. Like the cissoid, it was invented for the purpose of solving the famous problem of the "duplication of the cube"; it is, however, easily applied to the solution of the related, and no less famous, problem of the trisection of a given angle (see Note 3, below).

[^48]:    - It is evident that, if $A O<O B$, i.e., if $c<a$, the curve has an oval below A as shown in Fig 125; if $c=a$, this oval cloness up te a proint; and if $c>a$. both parts of the curve lie wholly above A.

    IFor the finertion of two mean propirtionals between two given lines by means of the conchoid, see Cantor, Geschichte der Mathemasik, Bd. I. S. 333.

[^49]:    - The witch was invented by Donna Maria Gaetana Agnesi (1718-1799), an Italian lady who was appointed professor of mathematics at the University of Bologna, in 1750.

[^50]:    - The lemnis ate was invented by Jacques Bernonilit (1064-1705), a noted Swise mathematician and professor in the Enivenity of Rasle. It his, howevir, only a sperial cave of the Casoiniain evala; vis, of the lucus of the vertex of a triangle whose lase is given in leugth and perition, and the producs of whose other two sides is a coustant. Sie Salmon's IIgher Plame Curves, 1. 41. Grugory's Examples, or Crauer's Introduction to the Analymis of Curves.

[^51]:    Note 1. The polar equation of the lemniscate is easily derived from equation (4) if the $x$-axis be chosen as initial line and the origin as pole;

[^52]:    - This curve was invented and named by Blaise Pascal (1623-166:-2), a celebrated French geometrician and philosopher. It is, however, a special case of the so-called Cartesian ovals.
    †Th limaçon may also be defined as the locus of the intersection of the two lines $O P$ and $C P$ which are so related during their revolution about $O$ and $C$, respectively, that the angle $X C P$ is always equal to it times the angle $X O P$. This definition easily leads to the polar equation already derived.

[^53]:    * This curve is historically interesting, because it is the first one which was rectified, i.e., it is the first one the length of an arc of which was expressed in rectilinear units. This celebrated rectification was performed, without the aid of the modern Calculus methods, by William Neil, a pupil of W allis (see Cantor, Geschichte der Mathematik, Bd. II., S. 827), in 1657 ; the curve is therefore called the Neilian parabola. It is also called the semicubical parabola because its equation may be written in the form $y=a x^{\frac{3}{2}}$.

[^54]:    * This curve may also be defined thus: It is the path traced by a point which moves away from the center with uniform linear velocity, while its radius vector revolves about the center with uniform angular velocity.

[^55]:    - See alsn Rice and Johnson's Differential Calculus, p. 307.

    1 This curve was invented and named by Cotes, who died in 1716.

[^56]:    - This curve might have been defined by maying that the radnus vector smereasess in a geometrie ratio while the veeturial angle incrowess in an arich. enetic ratio. Aft important property of this curve is (see M. Mahon and Snyder's Differential Caleulus, Art, 120) that it cuts all the midit vectores at the same angle, and the tangent of this angle lis the montulus of the system of logarithmas which the particular spiral reproseuts.

[^57]:    * With polar coördinates, these lines are a circle about the pole with radius $=\rho$, and a straight line through the pole making the angle $\theta$ with the initial line (Art. 28).
    $\dagger$ With polar coorrdinates, these surfaces are a sphere, about the origin as center, determined by the radius vector $\rho$, a right cone about the $z$-axis, with vertex at the origin, determined by the angle $\phi$, and a plane through the 2 -axis determined by the angle $\theta$ (Art. 201).

[^58]:    - See Chap. IV, where diagrams are given for the cornipponding cames of the general quadric, with elliptical instead of circular sections.

[^59]:    - The reduction of this article gives a second proof that the general algebraic equation of first degree always has for its locus a plane.

[^60]:    - If the cocflicients of two quadratic terms vanibh, an If and E, a change
     will reduce to the form (6).

[^61]:    - An exceptional case occurs where the general equation can be factored into linear factors, and therefore represents two planes.

[^62]:    - See Art 228.

[^63]:    - This fact is of importance in astronomy in ounnectson with the belavior of comets.

[^64]:    - Coaxial conics are, however, not necessarily confocal.
